व्यापक परिचालन मसौदा

हमारा संदर्भ: सीईडी 46 /टी-11

24 मार्च 2025

तकनीकी समिति: भारत की राष्ट्रीय भवन निर्माण विषय समिति, सीईडी 46

प्राप्तकर्ता :

1. सिविल अभियांत्रिकी विभाग परिषद, सीईडीसी के सभी सदस्य
2. राष्ट्रीय भवन निर्माण संहिता विषय समिति, सीईडी 46 के सभी सदस्य
3. सीईडी 46 की उपसीमितियों और अन्य कार्यदल के सभी सदस्य
4. रुचि रखने वाले अन्य निकाय।

महोदय/महोदया,

निम्नलिखित मानक का मसौदा संलग्न है:

प्रलेख संख्या	शीर्षक
सीईडी 46 (27022) WC	भारत की राष्ट्रीय भवन निर्माण संहिता भाग 6 संरचनात्मक डिजाइन अनुभाग 6 इस्पात और संमिश्र निर्माण : 6A इस्पात [SP7(भाग 6 अनुभाग 6A) का चौथा पुनरीक्षण] (आई सी एस नंबर: 01.120: 91.040.01)

कृपया इस मसौदे का अवलोकन करें और अपनी सम्मतियाँ यह बताते हुए भेजे कि यह मसौदा प्रकाशित हो तो इस पर अमल करने में आपको व्यवसाय अथवा कारोबार में क्या कठिनाइयाँ आ सकती हैं।

सम्मतियाँ भेजने की अंतिम तिथि: **25 अप्रैल 2025**

सम्मति यदि कोई हो तो कृपया अधोहस्ताक्षरी को ई-मेल द्वारा ced46@bis.gov.in पर या उपरलिखित पते पर, संलग्न फॉर्मेट में भेजें। सम्मतियाँ बीआईएस ई-गवर्नेंस पोर्टल, www.manakonline.in के माध्यम से ऑनलाइन भी भेजी जा सकती हैं।

यदि कोई सम्मति प्राप्त नहीं होती है अथवा सम्मति में केवल भाषा संबंधी त्रुटि हुई तो उपरोक्त प्रलेख को यथावत अंतिम रूप दे दिया जाएगा। यदि सम्मति तकनीकी प्रकृति की हुई तो विषय समिति के अध्यक्ष के परामर्श से अथवा उनकी इच्छा पर आगे की कार्यवाही के लिए विषय समिति को भेजे जाने के बाद प्रलेख को अंतिम रूप दे दिया जाएगा।

यह प्रलेख भारतीय मानक ब्यूरो की वेबसाइट www.bis.gov.in पर भी उपलब्ध है।
धन्यवाद।

WIDE CIRCULATION DRAFT

Our Reference: CED 46/T-11

24 March 2025

National Building Code of India Sectional Committee, CED 46

ADDRESSED TO:

1. All Members of Civil Engineering Division Council, CEDC
2. All Members of the National Building Code Sectional Committee, CED 46
3. All Members of Subcommittees, Panels and Working Groups under CED 46
4. All other interests

Dear Sir/Madam,

Please find enclosed the following draft:

Doc No.	Title
CED 46 (27022) WC	National Building Code of India Part 6 Structural Design Section 6 Steel and Composite Construction: 6A Steel [Fourth Revision of SP 7 (Part 6 Section 6A)] (ICS No. 01.120: 91.040.01)

Kindly examine the attached draft and forward your views stating any difficulties which you are likely to experience in your business or profession, if this is finally adopted as National Standard.

Last Date for comments: 25 April 2025

Comments if any, may please be made in the enclosed format and emailed at ced46@bis.gov.in or sent at the above address. Additionally, comments may be sent online through the BIS e-governance portal, www.manakonline.in.

In case no comments are received or comments received are of editorial nature, kindly permit us to presume your approval for the above document as finalized. However, in case comments, technical in nature are received, then it may be finalized either in consultation with the Chairman, Sectional Committee or referred to the Sectional Committee for further necessary action if so desired by the Chairman, Sectional Committee.

The document is also hosted on BIS website www.bis.gov.in.

Thanking you,

Yours faithfully,

Sd/-

(Dwaipayan Bhadra)

Scientist 'E' / Director and Head
(Civil Engineering Department)

Encl: As above

FORMAT FOR SENDING COMMENTS ON THE DOCUMENT

[Please use A4 size sheet of paper only and type within fields indicated. Comments on each clause/sub-clause/ table/figure, etc, be stated on a fresh row. Information/comments should include reasons for comments, technical references and suggestions for modified wordings of the clause. **Comments through e-mail to ced46@bis.gov.in shall be appreciated.**

LIST OF STANDARDS

FOREWORD

This Code (Part 6/Subsection 6A) covers the structural design aspects of steel structures in buildings.

This section covers the use of hot-rolled structural steel sections and steel tubes in buildings. It covers the design by limit state method and plastic theory.

This Section was first published in 1970 and revised in 1983, 2005 and 2016. In the second revision of 2005, the detailed design provisions were not included as IS 800 : 1984 'Code of practice for general construction in steel (*second revision*)' was under revision at that time. This Section, therefore, then referred to the 1984 version of IS 800 with the remarks that the latest version would prevail, as and when published. It, however, covered the philosophical aspects of limit state design which was being introduced in the revision of IS 800. IS 800 was subsequently revised and published as IS 800 : 2007 and hence, became the prevailing version for use under this Section. In the 2016 version of the NBC, the Section 6 of Part 6 of the Code was intended to bring it in line with the revised version of IS 800:2007 read with its Amendment No. 1 and to take care of further improvements and incorporations required.

In the revision of IS 800 in 20xx (*under preparation*), in view of the development and production of new varieties of medium and high-tensile structural steels in the country, the scope of the standard was modified, permitting the use of any variety of structural steel provided the relevant provisions of the standard were satisfied. IS 800: 20xx refers to the latest Indian Standards available for rivets, bolts, and other fasteners. The standard is based on the limit state method, reflecting the latest developments.

This revision of the Section is intended to bring it in line with the revised version of IS 800:20xx to take care of further improvements and incorporations required. In this revision, therefore, the following major modifications have been made:

- a) The working stress design has been discontinued due to the increasing familiarity of designers with the limit state design of steel structures.
- b) The table on tensile properties of structural steel products has been updated by including the Indian Standards relating to structural steels and aligning the corresponding provisions of the table with those given in IS 2062 : 20xx 'Hot rolled low, medium and high tensile structural steel (*eighth revision*)'.
- c) Fire-resistant steel as per IS 15103:2002 'Fire resistant steel – Specification', structural weather-resistant steels as per IS 11587:1986 'structural weather resistant steels – specification', and structural steels for buildings and structures with improved seismic resistance as per IS 15962:2012 'Structural steels for buildings and structures with improved seismic resistance – Specification' have been included in the table of tensile properties of structural steel products.
- d) Provisions related to the requirement of temperature stress analysis have been updated.

- e) Provisions related to the requirement of fire load have been updated.
- f) Table 2 Limiting width thickness ratio of elements has been updated
- g) Provisions related to the consideration of second order effects have been updated.
- h) Provisions related to design for earthquake loads relating to load and load combinations, various types of frames and connections in the critical zones of frames have been updated.
- j) Provisions related to bracing connections have been updated.
- k) Provisions related to fabrication procedures have been updated.
- m) Certain terminologies, symbols and figures have been updated based on the changes incorporated.
- n) Buckling class of cross section table has been updated.
- p) Imperfection parameter for lateral torsional buckling of beam has been added.
- q) A new clause on sustainable steel construction has been added. This provision covers the following:
 - 1) Requirements from Engineers, contractors and supply chain members,
 - 2) Sustainable design process by minimizing the materials, fabrication; and avoidance of maintenance,
 - 3) Design for adaptability and deconstruction, etc.
- r) The detailed provision relating to design of anchor bolts have been introduced in Annex G.
- s) The detailed provision relating to design of corrugated web girder has been introduced in Annex H.

The revised Section will enhance the confidence of designers, engineers, contractors, technical institutions, professional bodies and the industry and will open a new era in safe and economic construction in steel.

In the earlier versions of this Code, the provisions relating to using steel tubes in general building construction were based on IS 806: 1968 'Code of practice for the use of steel tubes in general building construction', which was complementary to IS 800. The design using tubular steel in structural applications may be carried out using the limit state design provisions in this Section until IS 806 is revised as per the limit state design method.

The design of cold-formed steel members is based on the provisions of IS 801 : 1975 'Code of practice for use of cold formed light gauge steel structural members in general building construction'. The standard is currently under revision to be based on the limit state design practice. Until the revised IS 801 is published, the cold formed steel members may be designed using the current IS 801, based on the working stress method.

All standards, whether given herein above or cross-referred to in the main text of this section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

For the purpose of deciding whether a particular requirement of this standard is complied with, the final value observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 'Rules for rounding of numerical values (*second revision*)'. The number of significant places retained in the rounded off value should be the same as that of the specified value in this standard.

Important Explanatory Note for Users of the Code

In any Part/Section of this Code, where reference is made to '**good practice**' in relation to **design, constructional procedures or other related information**, and where reference is made to "**accepted standard**" in relation to **material specification, testing, or other related information**, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/ Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practices [6-6A(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part/Section, that is, IS 786:1967 'Conversion factors and conversion tables (*first revision*)'.

DRAFT FOR COMMENTS ONLY

(Not to be reproduced without the permission of BIS or used as a Standard)

Draft Indian Standard

National Building Code of India

PART 6 STRUCTURAL DESIGN

Section 6 Steel and Composite Construction: 6A Steel

[Fourth Revision of SP 7 (Part 6/Section 6A)]

(ICS No. 01.120: 91.040.01)

**National Building Code Sectional
Committee, CED 46**

**Last Date for Comments:
25 April 2025**

1 SCOPE

1.1 This standard covers the structural design aspects of steel structures in buildings. This Section applies to general construction using hot rolled steel sections and steel tubes joined using riveting, bolting, and welding. Cold formed light gauge steel sections are covered in separate standards. This Section covers the design by limit state method and plastic theory.

1.2 This Section gives only general guidance as regards to the various loads to be considered in the design. For the actual loads, such as dead, live, snow, wind and earthquake loads and load combinations to be used, reference may be made to Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code.

1.3 Fabrication and erection requirements covered in this Section are general and the minimum necessary quality of material and workmanship consistent with assumptions in the design rules. The actual requirements may be further developed as per other standards or the project specification, the type of structure and the method of construction.

1.4 For seismic design, recommendations pertaining to steel frames only are covered in this section. For more detailed information on seismic design of other structural and non-structural components, reference be made to **5** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code and other special publications on the subject.

2 –

NOTE: This clause is intentionally left blank.

3 TERMINOLOGY

For the purpose of this section, the following definitions shall apply.

3.1 Accidental Loads — Loads due to explosion, impact of vehicles, or other rare loads for which the structure is considered to be vulnerable as per the user.

3.2 Accompanying Load — Imposed load acting along with leading imposed load but causing lower actions and/or deflections.

3.3 Action Effect or Load Effect — The internal force, axial, shear, bending or twisting moment, due to external actions and temperature loads.

3.4 Action — The primary cause for stress or deformations in a structure such as dead, imposed, wind, seismic or temperature loads.

3.5 Actual Length — The length between centre to centre of intersection points, with supporting members or the cantilever length in the case of a free standing member.

3.6 Beam — A member subjected predominantly to bending.

3.7 Bearing Type Connection — A connection made using bolts in ‘snug-tight’ condition, or rivets where the load is transferred by bearing of bolts or rivets against plate inside the bolt hole.

3.8 Braced Member — A member in which the relative transverse displacement is effectively prevented by bracing.

3.9 Brittle Cladding — Claddings, such as asbestos cement sheets which get damaged before undergoing considerable deformation.

3.10 Buckling Load — The load at which an element, a member or a structure as a whole, either collapses in service or buckles in a load test and develops excessive lateral (out of plane) deformation or instability.

3.11 Buckling Strength or Resistance — Force or moment, which a member can withstand without buckling.

3.12 Built-up Section — A member fabricated by interconnecting more than one element to form a compound section acting as a single member.

3.13 Camber — Intentionally introduced pre-curving (usually upwards) in a system, member or any portion of a member with respect to its chord. Frequently, camber is introduced to compensate for deflections at a specific level of loads.

3.14 Characteristic Load (Action) — The value of specified load (action), above which not more than a specified percentage (usually 5 percent) of samples of corresponding load are expected to be encountered.

3.15 Characteristic Yield/Ultimate Stress — The minimum value of stress, below which not more than a specified percentage (usually 5 percent) of corresponding stresses of samples tested are expected to occur.

3.16 Column — A member in upright (vertical) position which supports a roof or floor system and predominantly subjected to compression.

3.17 Compact Section — A cross section, which can develop plastic moment, but has inadequate plastic rotation capacity needed for formation of a plastic collapse mechanism of the member or structure.

3.18 Constant Stress Range — The amplitude between which the stress ranges under cyclic loading is constant during the life of the structure or a structural element.

3.19 Corrosion — An electrochemical process over the surface of steel, leading to oxidation of the metal.

3.20 Crane Load — Horizontal and vertical loads from cranes.

3.21 Cumulative Fatigue — Total damage due to fatigue loading of varying stress ranges.

3.22 Cut-off Limit — The stress range, corresponding to the particular detail, below which cyclic loading need not be considered in cumulative fatigue damage evaluation (corresponds to 10^8 number of cycles in most cases).

3.23 Dead Loads — The self-weights of all permanent constructions and installations including the self-weight of all walls, partitions, floors, roofs, and other permanent fixtures acting on a member.

3.24 Deflection — It is the deviation from the standard position of a member or structure.

3.25 Design Life — Time period for which a structure or a structural element is required to perform its function without damage.

3.26 Design Load/Factored Load — A load value obtained by multiplying the characteristic load with the partial safety factor for loads.

3.27 Design Spectrum — Frequency distribution of the stress ranges from all the nominal loading events during the design life (stress spectrum).

3.28 Detail Category — Designation given to a particular detail to indicate the S-N curve to be used in fatigue assessment.

3.29 Discontinuity — A sudden change in cross section of a loaded member, causing a stress concentration at the location.

3.30 Ductility — It is the property of the material or a structure indicating the extent to which it can deform beyond the limit of yield deformation before failure or fracture. The ratio of ultimate to yield deformation is usually termed as ductility.

3.31 Durability — It is the ability of a material to resist deterioration over long periods of time.

3.32 Earthquake effects — The inertia forces and relative deformations induced in a structure due to the ground shaking during an earthquake.

3.33 Edge Distance — Distance from the centre of a fastener hole to the nearest edge of an element measured perpendicular to the direction of load transfer.

3.34 Effective Lateral Restraint — Restraint that produces sufficient resistance to prevent deformation in the lateral direction.

3.35 Effective Length — Actual length of a member between points of effective restraint or effective restraint and free end, multiplied by a factor to take account of the end conditions in buckling strength calculations.

3.36 Elastic Cladding — Claddings, such as metal sheets that can undergo considerable deformation without damage.

3.37 Elastic Critical Moment — The elastic moment, which initiates lateral-torsional buckling of a laterally unsupported beam.

3.38 Elastic Design — Design, which assumes elastic behaviour of materials throughout the service load range.

3.39 Elastic Limit — It is the stress below which the material regains its original size and shape when the load is removed. In steel design, it is taken as the yield stress.

3.40 End Distance — Distance from the centre of a fastener hole to the edge of an element measured parallel to the direction of load transfer.

3.41 Erection Loads — The actions (loads and deformations) experienced by the structure exclusively during erection.

3.42 Erection Tolerance — Amount of deviation related to the plumbness, alignment, and level of the element as a whole in the erected position. The deviations are determined by considering the locations of the ends of the element.

3.43 Exposed Surface Area to Mass Ratio — The ratio of the surface area exposed to the fire (in mm²) to the mass of steel (in kg).

NOTE — In the case of members with fire protection material applied, the exposed surface area is to be taken as the internal surface area of the fire protection material.

3.44 Fabrication Tolerance — Amount of deviation allowed in the nominal dimensions and geometry in fabrication activities, such as cutting to length, finishing of ends, cutting of bevel angles, etc.

3.45 Factor of Safety — The factor by which the yield stress of the material of a member is divided to arrive at the permissible stress in the material.

3.46 Fatigue — Damage caused by repeated fluctuations of stress, leading to progressive cracking of a structural element.

3.47 Fatigue Loading — Set of nominal loading events, cyclic in nature, described by the distribution of the loads, their magnitudes and the numbers of applications in each nominal loading event.

3.48 Fatigue Strength — The stress range for a category of detail, depending upon the number of cycles it is required to withstand during design life.

3.49 Fire Exposure Condition

a) *Three-sided fire exposure condition* – Steel member incorporated in or in contact with a concrete or masonry floor or wall (at least against one surface).

NOTES

- 1 Three-sided fire exposure condition is to be considered separately unless otherwise specified (see **17.10**).

- 2 Members with more than one face in contact with a concrete or masonry floor or wall may be treated as three-sided fire exposure.

b) *Four-sided Fire Exposure Condition* – Steel member, which may be exposed to fire on all sides.

3.50 Fire Protection System — The fire protection material and its method of attachment to the steel member.

3.51 Fire Resistance — The ability of an element, component or structure, to fulfil for a stated period of time, the required stability, integrity, thermal insulation and/or other expected performance specified in a standard fire test.

3.52 Fire Resistance Level — The fire resistance grading period for a structural element or system, in minutes, which is required to be attained in the standard fire test.

3.53 Flexural Stiffness — Stiffness of a member against rotation as evaluated by the value of bending deformation moment required to cause a unit rotation while all other degrees of freedom of the joints of the member except the rotated one are assumed to be restrained.

3.54 Friction Type Connection — Connection effected by using pre-tensioned high strength bolts where shear force transfer is due to mobilization of friction between the connected plates due to clamping force developed at the interface of connected plates by the bolt pre-tension.

3.55 Gauge — The spacing between adjacent parallel lines of fasteners, transverse to the direction of load/stress.

3.56 Gravity Load — Loads arising due to gravitational effects.

3.57 Gusset Plate — The plate to which the members intersecting at a joint are connected.

3.58 High Shear — High shear condition is caused when the actual shear due to factored load is greater than a certain fraction of design shear resistance (see **16.2.2**).

3.59 Imposed (Live) Load — The load assumed to be produced by the intended use or occupancy including distributed, concentrated, impact, vibration and snow loads but excluding, wind, earthquake and temperature effects.

3.60 Instability — The phenomenon which disables an element, member or a structure to carry further load due to excessive deflection lateral to the direction of loading and vanishing stiffness.

3.61 Lateral Restraint for a Beam — See **3.34**.

3.62 Leading Imposed Load — Imposed load causing higher action and/or deflection.

3.63 Limit State — Any limiting condition beyond which the structure ceases to fulfill its intended function (see *also* **3.86**).

3.64 Live Load — See **3.59**.

3.65 Load — An externally applied force or action (see *also* **3.4**).

3.66 Main Member — A structural member, which is primarily responsible for carrying and distributing the applied load or action.

3.67 Mill Tolerance — Amount of variation allowed from the nominal dimensions and geometry, with respect to cross sectional area, non-parallelism of flanges, and out of straightness such as sweep or camber, in a product, as manufactured in a steel mill.

3.68 Normal Stress — Stress component acting normal to the face, plane or section.

3.69 Partial Safety Factor — The factor normally greater than unity by which either the loads (actions) are multiplied or the resistances are divided to obtain the design values.

3.70 Period of Structural Adequacy under Fire — The time (t), in minutes, for the member to reach the limit state of structural inadequacy in a standard fire test.

3.71 Permissible Stress — When a structure is being designed by the working stress method, the maximum stress that is permitted to be experienced in elements, members or structures under the nominal/service load (action).

3.72 Pitch — The centre to centre distance between individual fasteners in a line, in the direction of load/stress.

3.73 Plastic Collapse — The failure stage at which sufficient number of plastic hinges have formed due to the loads (actions) in a structure leading to a failure mechanism.

3.74 Plastic Design — Design against the limit state of plastic collapse.

3.75 Plastic Hinge — A yielding zone with significant inelastic rotation, which forms in a member, when the plastic moment is reached at a section.

3.76 Plastic Moment — Moment capacity of a cross section when the entire cross section has yielded due to bending moment.

3.77 Plastic Section — Cross section, which can develop a plastic hinge and sustain plastic moment over sufficient plastic rotation required for formation of plastic failure mechanism of the member or structure.

3.78 Poisson's Ratio — It is the absolute value of the ratio of lateral strain to longitudinal strain under uniaxial loading.

3.79 Proof Stress — The stress to which high strength friction grip (HSFG) bolts are pre-tensioned.

3.80 Proof Testing — The application of test loads to a structure, sub-structure, member or connection to ascertain the structural characteristics of only that specific unit.

3.81 Prototype Testing — Testing of structure, sub-structure, members or connections to ascertain the structural characteristics of that class of structures, sub-structures, members or connections that are nominally identical (full scale) to the units tested.

3.82 Prying Force — Additional tensile force developed in a bolt as a result of the flexing of a connection component such as a beam end plate or leg of an angle.

3.83 Rotation — The change in angle at a joint between the original orientation of two linear member and their final position under loading.

3.84 Secondary Member — Member which is provided for overall stability and or for restraining the main members from buckling or similar modes of failure.

3.85 Semi-compact Section — Cross section, which can attain the yield moment, but not the plastic moment before failure by plate buckling.

3.86 Serviceability Limit State — A limit state of acceptable service condition exceedance of which causes serviceability failure.

3.87 Shear Force — The in-plane force at any transverse cross section of a straight member of a column or beam.

3.88 Shear lag — The in plane shear deformation effect by which concentrated forces tangential to the surface of a plate gets distributed over the entire section perpendicular to the load over a finite length of the plate along the direction of the load.

3.89 Shear Stress — The stress component acting parallel to a face, plane or cross section.

3.90 Slender Section — Cross section in which the elements buckle locally before reaching yield moment.

3.91 Slenderness Ratio — The ratio of the effective length of a member to the radius of gyration of the cross section about the axis under consideration.

3.92 Slip Resistance — Limit shear that can be applied in a friction grip connection before slip occurs.

3.93 S-N Curve — The curve defining the relationship between the number of stress cycles to failure (N_{sc}) at a constant stress range (S_c), during fatigue loading of a structure.

3.94 Snow Load — Load on a structure due to the accumulation of snow and ice on surfaces such as roof.

3.95 Snug Tight — The tightness of a bolt achieved by a few impacts of an impact wrench or by the full effort of a person using a standard spanner.

3.96 Stability Limit State — A limit state corresponding to the loss of static equilibrium of a structure by excessive deflection transverse to the direction of predominant loads.

3.97 Stickability — The ability of the fire protection system to remain in place as the member deflects under load during a fire test.

3.98 Stiffener — An element used to retain or prevent the out-of-plane deformations of plates.

3.99 Strain — Deformation per unit length or unit angle.

3.100 Strain Hardening — The phenomenon of increase in stress with increase in strain beyond yielding.

3.101 Strength — Resistance to failure by yielding or buckling.

3.102 Strength Limit State — A limit state of collapse or loss of structural integrity.

3.103 Stress — The internal force per unit area of the original cross section.

3.104 Stress Analysis — The analysis of the internal force and stress condition in an element, member or structure.

3.105 Stress Cycle Counting — Sum of individual stress cycles from stress history arrived at using any rational method.

3.106 Stress Range — Algebraic difference between two extremes of stresses in a cycle of loading.

3.107 Stress Spectrum — Histogram of stress cycles produced by a nominal loading event design spectrum, during design life.

3.108 Structural Adequacy for Fire — The ability of the member to carry the test load exposed to the standard fire test.

3.109 Structural Analysis — The analysis of stress, strain, and deflection characteristics of a structure.

3.110 Strut — A compression member, which may be oriented in any direction.

3.111 Sway — The lateral deflection of a frame.

3.112 Sway Member — A member in which the transverse displacement of one end, relative to the other is not effectively prevented.

3.113 Tensile Stress — The characteristic stress corresponding to rupture in tension, specified for the grade of steel in the appropriate Indian Standard, as listed in Table 1.

3.114 Test Load — The factored load, equivalent to a specified load combination appropriate for the type of test being performed.

3.115 Transverse — Direction along the stronger axes of the cross section of the member.

3.116 Ultimate Limit State — The state which, if exceeded can cause collapse of a part or the whole of the structure.

3.117 Ultimate Stress — See 3.113.

3.118 Wind Loads — Load experienced by member or structure due to wind pressure acting on the surfaces.

3.119 Yield Stress — The characteristic stress of the material in tension before the elastic limit of the material is exceeded, as specified in the appropriate Indian Standard, as listed in Table 1.

3.120 Terms Relating to Sustainable Steel Design

3.120.1 Embodied Carbon – Life-cycle greenhouse gas emissions (expressed as carbon dioxide equivalents – CO₂e) that occur during the manufacture and transport of construction materials and components, as well as the construction process itself and end-of-life aspects of the building.

Note - In recent years, the term embodied carbon of construction materials and products has become synonymous with the term carbon footprint.

3.120.2 Deconstruction (or Disassembly, or Demounting) – Deconstruction is the process of taking a building apart into its components in such a way that they can be more readily reused; it minimizes the destructive aspects of the process of removing buildings, preserving components and materials not wasting them, and treating them as a resource.

3.120.3 *Design for Deconstruction (DfD)* – Designing for deconstruction is considering, at the design stage, how a building can be taken apart.

3.120.4 *Environmental Product Declaration (EPD)* – An EPD communicates verifiable, accurate, non-misleading environmental information for products and their applications; EPD information is expressed in information modules, which allow easy organization and expression of data packages throughout the life cycle of the product.

3.120.5 *Material Efficiency* – Optimizing the use of the steel by avoiding waste during fabrication and avoiding over specification of steel in the design.

3.120.6 *Recycling* – Steel involves re-melting of scrap to form new semi-finished products.

3.120.7 *Responsible Sourcing* – Management of sustainable development in the provision or procurement of a product.

3.120.8 *Reuse* – Use of previously used components with little or no reprocessing, largely in their original form; they may be reused for the original function (a conventional reuse scenario), or repurposed.

3.120.9 *Sustainable Development* – An enduring, balanced approach to economic activity, environmental responsibility and social progress.

3.120.10 *Traceability* – Ability to trace the history, application or location of an object.

4 SYMBOLS

For the purpose of this Subsection, the symbols (other than those used for load categorization) given in Annex A are applicable.

5 UNITS

For the purpose of design calculations the following units are recommended:

- a) Forces and loads, in kN, kN/m, kN/m²;
- b) Unit mass, in kg/m³;
- c) Unit weight, in kN/m³;
- d) Stresses and strengths, in N/mm² (= MN/m² or MPa); and
- e) Moments (bending, etc), in kNm.

For conversion of one system of units to another system, [6-6A(1)] may be referred.

6 STANDARD DIMENSIONS, FORM AND WEIGHT

The dimensions, form, weight, tolerances of all rolled shapes, all rivets, bolts, nuts, studs, and welds and other members used in any steel structure shall conform to accepted standards [6-6A(2)], wherever applicable.

7 PLANS AND DRAWINGS

7.1 Plans, drawings and stress sheet shall be prepared according to accepted standards [6-6A(3)].

7.1.1 Plans

The plans (design drawings) shall show the sizes, sections, and the relative locations of the various members. Floor levels, column centres, and offsets shall be dimensioned. Plans shall be drawn to a scale large enough to convey the information adequately. Plans shall indicate the type of construction to be employed; and shall be supplemented by such data on the assumed loads, shears, moments and axial forces to be resisted by all members and their connections, as may be required for the proper preparation of shop drawings. Any special precaution to be taken in the erection of structure, from the design consideration shall also be indicated in the drawing.

7.1.2 Shop Drawings

Shop drawings, giving complete information necessary for the fabrication of the component parts of the structure including the location, type, size, length and detail of all welds and fasteners shall be prepared in advance of the actual fabrication. They shall clearly distinguish between shop and field rivets, bolts and welds. For additional information to be included on drawings for designs based on the use of welding, reference shall be made to appropriate Indian Standards. Shop drawings shall be made in conformity with accepted standard [6-6A(4)]. A marking diagram allotting distinct identification marks to each separate part of steel work shall be prepared. The diagram shall be sufficient to ensure convenient assembly and erection at site.

7.2 Symbols used for welding on plans and shop drawings shall be according to good practice [6-6A(5)].

8 CONVENTION FOR MEMBER AXES

Unless otherwise specified convention used for member axes is as follows (Fig. 1)

- a) x-x along the member.
- b) y-y an axis of the cross section,
 - 1) perpendicular to the flanges, and
 - 2) perpendicular to the smaller leg in an angle section.
- c) z-z an axis of the cross-section
 - 1) axis parallel to flanges, and
 - 2) axis parallel to smaller leg in angle section.
- d) u-u major axis (when it does not coincide with z-z axis).
- e) v-v minor axis (when it does not coincide with y-y axis).

FIG. 1 AXES OF MEMBERS

9 MATERIALS

9.1 General

The material properties given in this Section are nominal values, to be accepted as characteristic values in design calculations.

9.2 Structural Steel

9.2.1 The provisions in this Section are applicable to the steels commonly used in steel construction namely, structural mild steel and high tensile structural steel.

9.2.2 All the structural steel used in general construction, coming under the purview of this standard shall before fabrication conform to accepted standard [6-6A(6)].

9.2.3 Structural steel other than those specified in **9.2.2** may also be used provided that the permissible stresses and other design provisions are suitably modified and the steel is also suitable for the type of fabrication adopted.

9.2.3.1 Steel that is not supported by mill test result may be used only in unimportant members and details, where their properties such as ductility and weldability would not affect the performance requirements of the members and the structure as a whole.

However, such steels may be used in structural system after confirming their quality by carrying out appropriate tests in accordance with the method specified in accepted standard [6-6A(7)].

9.2.4 Properties

The properties of structural steel for use in design may be taken as given in **9.2.4.1** and **9.2.4.2**.

9.2.4.1 Physical properties of structural steel irrespective of its grade may be taken as:

- a) Unit mass of steel, $\rho = 7\,850\text{ kg/m}^3$
- b) Modulus of elasticity, $E = 2.0 \times 10^5\text{ N/mm}^2\text{ (MPa)}$
- c) Poisson ratio, $\mu = 0.3$
- d) Modulus of rigidity, $G = 0.769 \times 10^5\text{ N/mm}^2\text{ (MPa)}$
- e) Coefficient of thermal expansion $\alpha_t = 12 \times 10^{-6}\text{ /}^\circ\text{C}$

9.2.4.2 Mechanical properties of structural steel

The principal mechanical properties of the structural steel important in design are the yield stress, f_y ; the tensile or ultimate stress, f_u ; the maximum percent elongation on a standard gauge length and notch toughness. Except for notch toughness, the other properties are determined by conducting tensile tests on samples cut from the plates, sections, etc, in accordance with accepted standard [6-6A(7)]. Commonly used properties for the common steel products of different specifications are summarized in Table 1.

9.2.4.2.1 Steel tubes – Steel tubes used in building construction shall be hot finished tubes conforming to the requirements specified in accepted standard [6-6A(8)].

9.2.4.2.2 Tubes made by other than hot finishing processes, or which have been subjected to cold working, shall be regarded as hot finished if they have subsequently been heat-treated and are supplied in the normalized conditions.

NOTE - Grade ERW YSt 22 tubes specified in accepted standard [6-6A(8)] with a carbon content less than 0.30 percent, may be considered as hot finished for the purpose of **9.2.4.2.2**.

9.4.2.4.3 Electrodes - The electrodes used for welding steel tubes shall conform to the requirements of accepted standard [6-6A(9)].

9.3 Rivets

9.3.1 Rivets shall be manufactured from steel conforming to accepted standard [6-6A(10)]. They may also be manufactured from steel conforming to accepted standard [6-6A(6)] provided that the steel meets the requirements given in accepted standard [6-6A(11)].

9.3.2 Rivets shall conform to accepted standards [6-6A(12)] as appropriate.

9.3.3 High Tensile Steel Rivets

High tensile steel rivets, shall be manufactured from steel conforming to accepted standard [6-6A(13)].

9.4 Bolts, Nuts and Washers

Bolts, nuts and washers shall conform as appropriate, to accepted standards [6-6A(14)]. The recommendations in good practice [6-6A(15)] shall be followed.

9.5 Steel Casting

Steel casting shall conform to accepted standard [6-6A(16)] or accepted standard [6-6A(17)].

9.6 Welding Consumable

9.6.1 Covered electrodes shall conform to accepted standard [6-6A(18)] or [6-6A(19)], as appropriate.

9.6.2 Filler rods and wires for gas welding shall conform to accepted standard [6-6A(20)].

9.6.3 The supply of solid filler wires for submerged arc welding of structural steels shall conform to accepted standard [6-6A(21)].

9.6.4 The bare wire electrodes for submerged arc welding shall conform to accepted standard [6-6A(22)]. The combination of wire and flux shall satisfy the requirements of accepted standard [6-6A(23)].

9.6.5 Filler rods and bare electrodes for gas shielded metal arc welding shall conform to accepted standards [6-6A(24)], as appropriate.

9.7 Other Materials

Other materials used in association with structural steel work shall conform to appropriate Indian standards.

NOTES

1 Percentage of elongation shall be taken over the gauge length of $5.65 \sqrt{S_0}$, where S_0 = original cross-sectional area of the test specimen.

2 Abbreviations: O = Ordinary, D = Drawing, DD = Deep Drawing, EDD = Extra Deep Drawing.

¹⁾ Stress at 0.2 percent non-proportional elongation, *Min*

10 GENERAL DESIGN REQUIREMENTS**10.1 Basis for Design****10.1.1 Design Objective**

The objective of design is the achievement of an acceptable probability that structures will perform satisfactorily for the intended purpose during the design life. With an appropriate degree of safety, they should sustain all the loads and deformations, during construction and use and have adequate resistance to certain expected accidental loads and fire. Structure should be stable and have alternate load paths to prevent disproportionate overall collapse under accidental loading.

10.1.2 Methods of Design

10.1.2.1 Structure and its elements shall normally, be designed by the limit state method. Account should be taken of accepted theories, experimental information and experience and the need to design for durability. Calculations alone may not produce safe, serviceable and durable structures. Suitable materials, quality control, adequate detailing and good supervision are equally important.

10.1.3 Design Process

Structural design, including design for durability, construction and use should be considered as a whole. The realization of design objectives requires compliance with clearly defined standards for materials, fabrication, erection and in-service maintenance.

10.2 Loads and Forces

10.2.1 For the purpose of designing any element, member or a structure, the following loads (actions) and their effects shall be taken into account, where applicable, with partial safety factors and combinations (see **12.3.3**).

- a) Dead loads;

- b) Imposed loads (live load, crane load, snow load, dust load, wave load, earth pressures, etc);
- c) Wind loads;
- d) Earthquake effects;
- e) Fire Load, forces induced due to restraint against expansion during a fire;
- f) Erection loads;
- g) Accidental loads such as those due to blasts, impact of vehicles, etc; and
- h) Secondary effects due to contraction or expansion resulting from temperature changes, differential settlements of the structure as a whole or of its components, eccentric connections, rigidity of joints differing from design assumptions.

10.2.1.1 Dead loads should be assumed in design as specified in **2** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code.

10.2.1.2 Imposed loads for different types of occupancy and function of structures shall be taken as recommended in **3** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code. Imposed loads arising from equipment, such as cranes and machines should be assumed in design as per manufacturers/suppliers data (see **10.5.4**). Snow load shall be taken as per in **6** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code.

10.2.1.3 Wind loads on structures shall be taken as per the recommendations of **4** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code.

10.2.1.3.1 *Wind pressure*

In calculating the effective wind pressure on exposed circular tube members of a structure, the effective area shall be taken as 0.6 times the projected area of the member (see **4** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects').

10.2.1.4 Earthquake effects shall be assumed as per the recommendations of **5** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code.

10.2.1.5 The erection loads and temperature effects shall be considered as specified in **10.3** and **10.4**, respectively.

10.3 Fire Loads

During a fire, the structural members around the fire experience higher temperatures. This causes expansion in members that is restrained by rest of the structure, inducing forces in the members. Simultaneously, due to high temperature both strength and stiffness of the members experiencing the higher temperature degrade. The forces in members during fire including that due to dead load and imposed load are checked against the reduced capacity of the members. As it is an extreme event, the design is done for loads without extra partial safety factors. The imposed load is taken as 100 percent of the characteristic loads in case of storage areas and otherwise taken as 50 percent of the characteristic value, during fire.

10.4 Erection Loads

All loads required to be carried by the structure or any part of it due to storage or positioning of construction material and erection equipment, including all loads due to operation of such equipment shall be considered as erection loads. Proper provision shall be made, including temporary bracings, to take care of all stresses developed during erection. Dead load, wind load and also such parts of the imposed load as would be imposed on the structure during the period of erection shall be taken as acting together with the erection loads. The structure as a whole and all parts of the structure in conjunction with the temporary bracings shall be capable of sustaining these loads during erection.

10.5 Temperature Effects

10.5.1 Expansion and contraction due to changes in temperature of the members and elements of a structure shall be considered and adequate provision made for such effect.

10.5.2 The temperature range varies for different localities and under different diurnal and seasonal conditions. The absolute maximum and minimum temperatures, which may be expected in different localities of the country, may be obtained from the Indian Metrological Department and used in assessing the maximum variations of temperature for which provision for expansion and contraction has to be made in the structure.

10.5.3 The range of variation in temperature of the building materials may be appreciably greater or lesser than the variation of air temperature and is influenced by the condition of exposure and the rate at which the materials composing the structure absorb or radiate heat. This difference in temperature variations of the material and air shall be given due consideration. The effect of differential temperature within an element or member, due to part exposure to direct sunlight shall also be considered.

10.5.4 The coefficient of thermal expansion for steel is as given in **9.2.4.1(e)**.

10.6 Load Combinations

10.6.1 Load combinations for design purposes shall be those that produce maximum forces and effects and, consequently maximum stresses and deformations. The following combination of loads with appropriate partial safety factors (see Table 4) may be considered:

- a) Dead load + Imposed load,
- b) Dead load + Imposed load + Wind or Earthquake load,
- c) Dead load + Wind or Earthquake load,
- d) Dead Load+ Imposed loads+ Effects of Fire, and
- e) Dead load + Erection load.

NOTE – In the case of structures supporting cranes, imposed loads shall include the crane effects as given in **10.6.4**.

10.6.2 Wind load and earthquake effects shall not be assumed to act simultaneously. The effect of each shall be considered separately.

10.6.3 The effect of cranes to be considered under imposed loads shall include the vertical loads, eccentricity effects induced by the vertical loads, impact factors, lateral (surge) and longitudinal (horizontal) thrusts, not acting simultaneously across and along the crane rail, respectively [see **3** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code].

10.6.4 The crane loads and their combinations to be considered shall be as indicated by the customer. In the absence of any specific indications, the load combinations shall be in accordance with the provisions in **3** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code or as given below:

- a) Vertical loads with full impact from one loaded crane or two cranes in case of tandem operation, together with vertical loads without impact from as many loaded cranes as may be positioned for maximum effect, along with maximum horizontal thrust from one crane only or two in case of tandem operation;
- b) Loads as specified in **10.5.4(a)**, subject to cranes in maximum of any two bays of the building cross section shall be considered for multi-bay multi-crane gantries;
- c) The longitudinal thrust on a crane track rail shall be considered for a maximum of two loaded cranes on the track; and
- d) Lateral thrust (surge) and longitudinal thrust acting across and along the crane rail, respectively, shall be assumed not to act simultaneously. The effect of each force, shall however be investigated separately.

10.6.5 While investigating the effect of earthquake, the resulting effect from dead loads of all cranes parked in each bay, positioned to cause maximum effect shall be considered.

10.6.6 The crane runway girders supporting bumpers shall be checked for bumper impact loads also, as specified by the manufacturers.

10.6.7 Stresses developed due to secondary effects such as handling; erection, temperature and settlement of foundations, if any, shall be appropriately added to the stresses calculated from the combination of loads stated in **10.5.1**, with appropriate partial safety factors.

10.7 Geometrical Properties

10.7.1 General

The geometrical properties of the gross and the effective cross sections of a member or part thereof, shall be calculated on the following basis:

- a) The properties of the gross cross section shall be calculated from the specified size of the member or part thereof or read from appropriate table.

b) The properties of the effective cross section shall be calculated by deducting from the area of the gross cross section, in the following:

- 1) The sectional area in excess of effective plate width, in case of slender sections (see **10.8.2 d**).
- 2) The sectional areas of all holes in the section except for parts in compression. In case of punched holes, hole size 2 mm in excess of the actual diameter may be deducted.

10.8 Classification of Cross Sections

10.8.1 Plate elements of a cross section may buckle locally due to compressive stresses. The local buckling can be avoided before the limit state is achieved by limiting the width to thickness ratio of each element of a cross section subjected to compression due to axial force, moment or shear.

10.8.1.1 When plastic analysis is used, the members shall be capable of forming plastic hinges with sufficient rotation capacity (ductility) without local buckling, to enable the redistribution of bending moment required before formation of the failure mechanism.

10.8.1.2 When elastic analysis is used, the member shall be capable of developing the yield stress under compression without local buckling.

10.8.2 On basis of the above, four classes of sections are defined as follows:

- a) *Class 1 (Plastic)* – Cross sections, which can develop plastic hinges and have the rotation capacity required for failure of the structure by formation of plastic mechanism. The width to thickness ratio of plate elements shall be less than that specified under Class 1 (Plastic), in Table 2.
- b) *Class 2 (Compact)* – Cross sections, which can develop plastic moment of resistance, but have inadequate plastic hinge rotation capacity for formation of plastic mechanism, due to local buckling. The width to thickness ratio of plate elements shall be less than that specified under Class 2 (Compact), but greater than that specified under Class 1 (Plastic), in Table 2.
- c) *Class 3 (Semi-compact)* – Cross sections, in which the extreme fiber in compression can reach yield stress, but cannot develop the plastic moment of resistance, due to local buckling. The width to thickness ratio of plate elements shall be less than that specified under Class 3 (Semi-compact), but greater than that specified under Class 2 (Compact), in Table 2.
- d) *Class 4 (Slender)* – Cross sections in which the elements buckle locally even before reaching yield stress. The width to thickness ratio of plate elements shall be greater than that specified under Class 3 (Semi-compact), in Table 2. In such cases, the effective sections for design shall be calculated either by following the provisions of good practice [6-6A(35)] to account for the post-local-buckling strength or by conservatively deducting width of the compression plate element in excess of the semi-compact section limit (see Fig. 2b and Fig. 2c).

The design of slender web elements in flexural members may be done as given in **15.2.1.1** for flexure and **15.4.2.2** for shear.

When different elements of a cross section fall under different classes, the section shall be classified as governed by the most critical element.

The maximum value of limiting width to thickness ratios of elements for different classifications of sections are given in Fig. 2A. The effective section in case of class 4 (slender elements) may be conservatively taken as shown in Fig. 2B and Fig. 2C.

10.8.3 Types of Elements

- a) *Internal elements* – These are elements attached along both longitudinal edges to other elements or to longitudinal stiffeners connected at suitable intervals to transverse stiffeners; for example web of I-section and flanges and web of box section.
- b) *Outside elements or outstands* – These are elements attached along only one of the longitudinal edges to an adjacent element, the other edge being free to displace out of plane, for example flange overhang of an I-section, stem of T-section and legs of an angle section.
- c) *Tapered elements* – These may be treated as flat elements having average thickness as defined in accepted standard [6-6A(36)].

The design of slender compression element (Class 4) considering the strength beyond elastic local buckling of element is outside the scope of this section. Reference may be made to in good practice [6-6A(35)] for such design provisions. The design of slender web elements may be made as given in **15.2.1.1** for flexure and **15.4.2.2** for shear.

10.8.4 Compound Elements in Built-up Section (see Fig. 2)

In case of compound elements consisting of two or more elements bolted or welded together, the limiting width to thickness ratios as in Table 2 should be considered on basis of the following:

- a) Outstanding width of compound element (b_e) to its own thickness.
- b) The internal width of each added plate between the lines of welds or fasteners connecting it to the original section to its own thickness.
- c) Any outstand of the added plates beyond the line of welds or fasteners connecting it to original section to its own thickness.

Table 2 Limiting Width to Thickness Ratio
(Clauses 10.7.2 and 10.7.4)

SI No.	Compression Element			Ratio	Class of Section		
					Class 1 Plastic	Class 2 Compact	Class 3 Semi-compact
(1)	(2)			(3)	(4)	(5)	(6)
i)	Outstanding element	Under uniform compression		b/t	8.7ε	9.7ε	13.6ε
		Non uniform stress	Tip in compression	b/t	$\frac{8.7\varepsilon}{r_1}$	$\frac{9.7\varepsilon}{r_1}$	---
			Tip in tension	b/t	$\frac{8.7\varepsilon}{r_1\sqrt{r_1}}$	$\frac{9.7\varepsilon}{r_1\sqrt{r_1}}$	---
ii)	Web of I, Channel, H or box section	Axial compression		b/t	32ε	36.8ε	40.7ε
		Non uniform stress	Neutral axis at mid-depth	d/t_w	70ε	80ε	120ε
			$r_1 > 0.5$ (or) $r_2 > -1$	d/t_w	$\frac{384\varepsilon}{13r_1 - 1}$	$\frac{442\varepsilon}{13r_1 - 1}$	$\frac{40.7\varepsilon}{0.67 + 0.33r_2}$
			$r_1 \leq 0.5$ (or) $r_2 > -1$	d/t_w	$\frac{35\varepsilon}{r_1}$	$\frac{40.2\varepsilon}{r_1}$	$60\varepsilon(1 - r_2)\sqrt{(r_2)}$
iii)	Angle, compression due to bending (Both criteria should be satisfied)			b/t	8.7ε	9.7ε	14.5ε
				d/t	8.7ε	9.7ε	14.5ε
iv)	Single angle, or double angles with the components separated, axial compression (All three criteria should be satisfied)			b/t d/t $(b+d)/t$	Not applicable		14.5ε 14.5ε 22.3ε
v)	Outstanding leg of an angle in contact back-to-back in a double angle member or with another component			d/t	8.7ε	9.7ε	14.5ε
vi)	Circular hollow tube, including welded tube	a) moment		D/t	$47\varepsilon^2$	$66\varepsilon^2$	$85\varepsilon^2$
		b)axial compression		D/t	Not applicable		$86\varepsilon^2$
NOTES							
1 Elements which exceed semi-compact limits are to be taken as of slender cross section							
2 $\varepsilon = (250 / f_y)^{1/2}$							
3 Webs shall be checked for shear buckling in accordance with 15.4.2 when $d/t > 67\varepsilon$. Where, b is the width of the element may be taken as clear distance between lateral supports or between lateral support and free edge, as appropriate, t is the thickness of element, d is the depth of the web, D is the outer diameter of the element (see Fig 2, 10.8.3 and 10.8.4).							
4 Different elements of a cross section can be in different classes. In such cases the section is classified based on the least favourable classification.							
5 The stress ratio r_1 and r_2 are defined as:							
$r_1 = \frac{\text{depth under compression}}{\text{Overall depth}}$							
$r_2 = \frac{\text{Minimum compressive stress (tensile if negative)}}{\text{Maximum compressive stress}}$

FIG. 2 CLASSIFICATION OF SECTIONS

10.9 Maximum Effective Slenderness Ratio

10.9.1 The maximum effective slenderness ratio, KL/r , values of a beam, strut or tension member shall not exceed those given in Table 3. 'KL' is the effective length of the member and 'r' is appropriate radius of gyration based on the effective section as defined in **10.7.1**.

Table 3 Maximum Values of Effective Slenderness Ratios
(Clause 10.9.1)

Sl No.	Member	Maximum Effective Slenderness Ratio KL/r
(1)	(2)	(3)
i)	A member carrying compressive loads resulting from dead loads and imposed loads	180
ii)	A tension member in which a reversal of direct stress occurs due to loads other than wind or seismic forces	180
iii)	A member subjected to compression forces resulting only from combination with wind/earthquake effects, provided the deformation of such member does not adversely affect the stress in any part of the structure	250
iv)	Compression flange of a beam against lateral torsional buckling	300
v)	A member normally acting as a tie in a roof truss or a bracing system not considered effective when subject to possible reversal of stress into compression resulting from the action of wind or earthquake effects ¹⁾	350
vi)	Members always under tension ¹⁾ (other than pre-tensioned members)	400

¹⁾ Tension members, such as bracings, where sag is avoided, need not satisfy the maximum slenderness ratio limits.

10.11 Resistance to Horizontal Forces

10.11.1 In designing the steel frame work of a building, provision shall be made (by adequate moment connections or by a system of bracing) to effectively transmit to the foundations all the horizontal forces, giving due allowance for the stiffening effect of the walls and floors, where applicable.

10.11.2 When the walls, or walls and floors and/or roofs are capable of effectively transmitting all the horizontal forces directly to the foundations, the structural steel framework may be designed without considering the effects of wind or earthquake.

10.11.3 Wind and earthquake effects are reversible and therefore call for initial stiffness and strength under force reversal in both longitudinal and transverse directions. To resist torsional effects of wind and earthquake forces, bracings in plan should be provided and integrally connected with the longitudinal and transverse bracings, to impart adequate torsional resistance to the structure.

10.11.3.1 In shed type steel mill buildings, adequate bracings shall be provided to transfer the wind or earthquake loads from their points of action to the appropriate supporting members. Where the connections to the interior columns or frames are designed such that the wind or earthquake loads will not be transferred to the interior columns, the exterior columns or frames shall be designed to resist the total wind or earthquake loads. Where the connections to the interior columns and frames are designed such that the wind or earthquake effects are transferred to the interior columns also, and where adequate rigid diaphragm action can be mobilized as in the case of the cast-in place RC slab, both exterior and interior columns and frames may be designed on the assumption that the wind or earthquake load is divided among them in proportion to their relative stiffness. Columns also should be designed to withstand the net uplifting effect caused by excessive wind or earthquake shaking. Additional axial forces arising in adjacent columns due to the vertical component of bracings or due to frame action shall also be accounted for.

10.11.3.2 Earthquake forces are proportional to the seismic mass as defined in **5** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code. Earthquake forces should be applied at the centre of mass of all such components and their transfer to the foundation should be ensured. Other construction details, stipulated in good practice [6-6A(37)] should also be followed.

10.11.3.3 In buildings where high-speed traveling cranes are supported or where a building or structure is otherwise subjected to vibration or sway, triangulated bracing or rigid portal systems shall be provided to reduce the vibration or sway to an acceptable minimum.

10.11.4 *Foundations*

The foundations of a building or other structures shall be designed to provide the rigidity and strength that has been assumed in the analysis and design of the superstructure.

10.11.5 *Eccentrically Placed Loads*

Where a wall, or other gravity load, is placed eccentrically upon the flange of a supporting steel beam, the beam and its connections shall be designed for torsion, unless the beam is restrained laterally in such a way as to prevent the twisting of the beam.

10.12 **Expansion Joints**

Expansion joints in case of low-rise buildings shall comply with **10.11.1** to **10.11.4**. For requirement of expansion joints in high-rise buildings, specialist literature shall be referred to.

10.12.1 In view of the large number of factors involved in deciding the location, spacing and nature of expansion joints, the decision regarding provision of expansion joints shall be left to the discretion of the designer.

10.12.2 Structures in which marked changes in plan dimensions take place abruptly, shall be provided with expansion joints at the section where such changes occur. Expansion joints shall be so provided that the necessary movement occurs with minimum resistance at the joint. The gap at the expansion joint should be such that;

- a) it accommodates the expected expansion/contraction due to seasonal and diurnal variation of temperature; and
- b) it avoids pounding of adjacent units under earthquake shaking. The structure adjacent to the joint should preferably be supported on separate columns but not necessarily on separate foundations.

10.12.3 The details as to the length of a structure where expansion joints have to be provided may be determined after taking into consideration various factors such as temperature, exposure to weather and structural design. The provisions in **10.12.3.1** to **10.12.3.3** are given as general guidance. The provision for expansion may be made by providing double framing at the joint or providing for expansion at the connection to the single framing in detailing.

10.12.3.1 If one bay of longitudinal bracing is provided at the centre of the building or building section, the length of the building section may be restricted to 180 m in case of covered buildings and 120 m in case of open gantries (see Fig. 3).

10.12.3.2 If more than one bay of longitudinal bracing is provided near the centre of the building/section, the maximum centre line distance between the two lines of bracing may be restricted to 50 m for covered buildings (and 30 m for open gantries) and the maximum distance between the centre of the bracing to the nearest expansion joint/end of building or section may be restricted to 90 m (60 m in case of open gantries). The maximum length of the building section thus may be restricted to 230 m for covered buildings (150 m for open gantries). Beyond this, suitable expansion joints shall be provided (see Fig.4).

10.12.3.3 The maximum width of the covered building section should preferably be restricted to 150 m beyond which suitable provisions for the expansion joint may be made.

10.12.4 When the provisions of these sections are met for a building or open structure made only of steel frame with elastic steel claddings, the stress analysis due to temperature is not required. However, for buildings, specialist literature may be referred to decide on thermal stress design.

FIG. 3 MAXIMUM LENGTH OF BUILDING WITH ONE BAY OF BRACING

FIG. 4 MAXIMUM LENGTH OF COVERED BUILDING/SECTION WITH TWO BAYS OF BRACINGS

11 METHODS OF STRUCTURAL ANALYSIS

11.1 Methods of Determining Action Effects

11.1.1 General

For the purpose of complying with the requirements of the limit states of stability, strength and serviceability specified under **12** effects of design actions on a structure and its members and connections, shall be determined by structural analysis using the assumptions of **11.2** and **11.3** and one of the following methods of analysis:

- Elastic analysis in accordance with **11.4**,
- Plastic analysis in accordance with **11.5**,
- Advanced analysis in accordance with Annex B, or
- Dynamic analysis in accordance with **5** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code.

The effects of design earthquake shaking specified in **18** shall be estimated by elastic analysis. Plastic analysis shall not be employed to obtain member forces corresponding to design earthquake shaking specified in **18**. More information on analysis to resist earthquake effects is given in **5** of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code.

11.1.2 Non-sway and Sway Frames

For the purpose of analysis and design, the structural frames are classified as non-sway and sway frames as given below:

- Non-sway frame* — One in which the transverse displacement of one end of the member relative to the other end is effectively prevented. This applies to triangulated frames and trusses or to frames where in-plane stiffness is provided by bracings, or by shear walls, or by floor slabs and roof decks secured horizontally to walls or to bracing systems parallel to the plane of loading and bending of the frame.

- b) *Sway frame* — One in which the transverse displacement of one end of the member relative to the other end is not effectively prevented. Such members and frames occur in structures which depend on flexural action of members to resist lateral loads and sway, as in moment resisting frames.
- c) A rigid jointed multi-storey frame may be considered as a non-sway frame if in every individual storey, the deflection δ , over a storey height h_s , due to the notional horizontal loading given in **11.3.6** satisfies the following criteria:

- 1) For clad frames, when the stiffening effect of the cladding is not taken into account in the deflection calculations:

$$\delta \leq \frac{h_s}{2000}$$

- 2) For unclad frame or clad frames, when the stiffening effect of the cladding is taken into account in the deflection calculations:

$$\delta \leq \frac{h_s}{4000}$$

- 3) A frame, which when analyzed considering all the lateral supporting system does not comply with the above criteria, should be classified as a sway frame, even if it is braced or otherwise laterally stiffened.

11.2 Forms of Construction Assumed for Structural Analysis

11.2.1 The effects of design action in the members and connections of a structure shall be determined by assuming singly or in combination of the following forms of construction (see **17.6.1**).

11.2.1.1 *Rigid construction*

In rigid construction, the connections between members (beam and column) at their junction shall be assumed to have sufficient rigidity to hold the original angles between the members connected at a joint unchanged under loading.

11.2.1.2 *Semi-rigid construction*

In semi-rigid construction, the connections between members (beam and column) at their junction may not have sufficient rigidity to hold the original angles between the members at a joint unchanged, but shall be assumed to have the capacity to furnish a dependable and known degree of flexural restraint. The relationship between the degree of flexural restraint and the level of the load effects shall be established by any rational method or based on test results (see Annex F).

11.2.1.3 *Simple construction*

In simple construction, the connections between members (beam and column) at their junction will not resist any appreciable moment and shall be assumed to be hinged.

11.2.2 *Design of connections*

The design of all connections shall be consistent with the form of construction, and the behaviour of the connections shall not adversely affect any other part of the structure beyond what is allowed for in design. Connections shall be designed in accordance with provisions under 17.

11.3 Assumptions in Analysis

11.3.1 The structure shall be analyzed in its entirety except as follows:

- a) Regular building structures, with orthogonal frames in plan, may be analyzed as a series of parallel two-dimensional sub-structures (part of a structure), the analysis being carried out in each of the two directions, at right angles to each other, except when there is significant load redistribution between the sub-structures (part of a structure).
- b) For vertical loading in a multi-storey building structure, provided with bracing or shear walls to resist all lateral forces, each level thereof, together with the columns immediately above and below, may be considered as a substructure, the columns being assumed fixed at the ends remote from the level under consideration.
- c) Where beams at a floor level in a multi-bay building structure are considered as a substructure (part of a structure), the bending moment at the support of the beam due to gravity loads may be determined based on the assumption that the beam is fixed at the far end support, one span away from the span under consideration, provided that the floor beam is continuous beyond that support point.

11.3.2 *Span Length*

The span length of a flexural member in a continuous frame system shall be taken as the centre-to-centre distance between the supports.

11.3.3 *Arrangements of Imposed Loads in Buildings*

For building structures, the various arrangements of imposed loads considered for the analysis, shall include at least the following:

- a) Where the loading pattern is fixed, the arrangement concerned.
- b) Where the imposed load is variable and not greater than three-quarters of the dead load, the imposed load may be taken to be acting on all spans.
- c) Where the imposed load is variable and exceeds three-quarters of the dead load, arrangements of imposed load acting on the floor under consideration shall include the following cases:
 - 1) Imposed load on alternate spans,
 - 2) Imposed load on two adjacent spans, and
 - 3) Imposed load on all the spans.

11.3.4 Base Stiffness

In the analysis of all structures, the appropriate base stiffness about the axis under consideration shall be used. In the absence of the knowledge of the pedestal and foundation stiffness, the following may be assumed:

- a) When the column is rigidly connected to a suitable foundation, the stiffness of the pedestal shall be taken as the stiffness of the column above base plate. However, in case of very stiff pedestals and foundations the column may be assumed as fixed at base.
- b) When the column is nominally connected to the foundation, a pedestal stiffness of 10 percent of the column stiffness may be assumed.
- c) When an actual pin or rocker is provided in the connection between the steel column and pedestal, the column is assumed as hinged at base and the pedestal and foundation may be appropriately designed for the reactions from the column.
- d) In case of (a) and (b), the bottom of the pedestal shall be assumed to have the following boundary condition in the absence of any detailed procedure based on theory or tests:
 - 1) When the foundation consists of a group of piles with a pile cap, raft foundation or an isolated footing resting on rock or very hard soil, the pedestal shall be assumed to be fixed at the level of the bottom of footing or at the top of the pile cap.
 - 2) When the foundation consists of an isolated footing resting on other soils, the pedestal shall be assumed to be hinged at the level of the bottom of the footing.
 - 3) When the pedestal is supported by a single pile, which is laterally surrounded by soil providing passive resistance, the pile shall be assumed to be fixed at a depth of 5 times the diameter of the pile below the ground level in case of compact ground or the top level of compact soil in case of poor soil overlying compact soil.
 - 4) When the column is founded into rock, it may be assumed to be fixed at the interface of the column and rock.

11.3.5 Simple Construction

Bending members may be assumed to have their ends connected for shear only and to be free to rotate. In triangulated structures, axial forces may be determined by assuming that all members are pin-connected. The eccentricity for stanchion and column shall be assumed in accordance with **14.3.3**.

11.3.6 Notional Horizontal Loads

To analyze a frame subjected to gravity loads, considering the sway stability of the frame, notional horizontal forces should be applied. These notional horizontal forces account for practical imperfections and should be taken at each level as being equal to 0.5 percent of factored dead load plus vertical imposed loads applied at that level. The notional load

should not be applied along with other lateral loads, such as wind and earthquake effects, in the analysis.

11.3.6.1 The notional forces should be applied on the whole structure, in both orthogonal directions, in one direction at a time, at roof and all floor levels or their equivalent. They should be taken as acting simultaneously with factored gravity loads.

11.3.6.2 The notional force should not be,

- a) applied when considering overturning or overall instability;
- b) combined with other horizontal (lateral) loads;
- c) combined with temperature effects, and
- d) taken to contribute to the net shear on the foundation.

11.3.6.3 The sway effect using notional load under gantry load case need not be considered if the ratio of height to lateral width of the building is less than unity.

11.4 Elastic Analysis

11.4.1 Assumptions

Individual members shall be assumed to remain elastic under the action of the factored design loads for all limit states.

The effect of haunching or any variation of the cross section along the axis of a member shall be considered, and where significant, shall be taken into account in the determination of the member stiffness.

11.4.2 First-order Elastic Analysis

11.4.2.1 In a first-order elastic analysis, the equilibrium of the frame in the undeformed geometry is considered, the changes in the geometry of the frame due to the loading are not accounted for, and changes in the effective stiffness of the members due to axial force are neglected. The conditions under which the first order elastic analysis results are adequate for design are given in Section **11.7**.

11.5 Plastic Analysis

11.5.1 Application

The effects of design action throughout or on part of a structure may be determined by a plastic analysis, provided that the requirements of **11.5.2** are met. The distribution of design action effects shall satisfy equilibrium and the boundary conditions.

11.5.2 Requirements

When a plastic method of analysis is used, all of the following conditions shall be satisfied, unless adequate ductility of the structure and plastic rotation capacity of its members and connections are established for the design loading conditions by other means of evaluation:

- a) The yield stress of the grade of the steel used shall not exceed 450 MPa.
- b) The stress-strain characteristics of the steel shall not be significantly different from those obtained for steels complying with the accepted standard [6-6A(6)] or equivalent and shall be such as to ensure complete plastic moment redistribution. The stress-strain diagram shall have a plateau at the yield stress, extending for at least six times the yield strain. The ratio of the tensile strength to the yield stress specified for the grade of the steel shall not be less than 1.2. The elongation on a gauge length complying with the accepted standard [6-6A(6)] shall not be less than 15 percent; and the steel shall exhibit strain-hardening capability. Steels conforming to the accepted standard [6-6A(6)] shall be deemed to satisfy the above requirements.
- c) The members used shall be hot-rolled or fabricated using hot-rolled plates and sections.
- d) The cross section of members not containing plastic hinges should be at least that of compact section (see **10.7.2**), unless the members meet the strength requirements from elastic analysis.
- e) Where plastic hinges occur in a member, the proportions of its cross section should not exceed the limiting values for plastic section given in **10.7.2**.
- f) The cross section should be symmetrical about its axis perpendicular to the axis of the plastic hinge rotation.
- g) The members shall not be subject to impact loading, requiring fracture assessment or fluctuating loading, requiring a fatigue assessment [see **19**].

11.5.2.1 Restraints

If practicable, torsional restraint (against lateral buckling) should be provided at all plastic hinge locations. Where not feasible, the restraint should be provided within a distance of $D/2$ of the plastic hinge location, where D is the total depth of section.

The torsional restraint requirement at a section as above, need not be met at the last plastic hinge to form, provided it can be clearly identified.

Within a member containing a plastic hinge, the maximum distance L_m from the restraint at the plastic hinge to an adjacent restraint should be calculated by any rational method or the conservative method given below, so as to prevent lateral buckling.

Conservatively L_m (in mm) may be taken as:

$$L_m \leq \frac{38r_y}{\left[\frac{f_c}{130} + \left(\frac{f_y}{250} \right)^2 \left(\frac{x_t}{40} \right)^2 \right]^{1/2}}$$

where

f_c = actual compressive stress on the cross section due to axial load, in N/mm²,
 f_y = yield stress, in N/mm²;
 r_y = radius of gyration about the minor axis, in mm;
 x_t = torsional index, $x_t = 1.132 (A I_w / I_y I_t)^{0.5}$;
 A = area of cross section; and
 I_w, I_y, I_t = warping constant, second moment of the cross section about the minor axes and St. Venant's torsion constant, respectively.

Where the member has unequal flanges, r_y should be taken as the lesser of the values of the compression flange only or the whole section.

Where the cross section of the member varies within the length L_m , the maximum value of r_y and the minimum value of x_t should be used.

The spacing of restraints to member lengths not containing a plastic hinge should satisfy the recommendations of section on lateral buckling strength of beams (see **15.2.2**). Where the restraints are placed at the limiting distance L_m , no further checks are required.

11.5.2.2 Stiffeners at plastic hinge locations

Web stiffeners should be provided where a concentrated load, which exceeds 10 percent of the shear capacity of the member, is applied within $D/2$ of a plastic hinge location, (see **15.2.1.2**). The stiffener should be provided within a distance of half the depth of the member on either side of the hinge location and be designed to carry the applied load in accordance with **15.7.4**. If the stiffeners are flat plates, the outstand width to the thickness ratio, b/t , should not exceed the values given in the plastic section (see **10.7** and Table

2). Where other sections are used, the ratio $\left(\frac{I_{so}}{I_t} \right)^{1/2}$, should not exceed the values given for plastic section (for simple outstand, as in **10.7**);

where

I_{so} = second moment of area of the stiffener about the face of the element perpendicular to the web; and
 I_t = St. Venant's torsion constant of the stiffener.

11.5.2.3 The frame shall be adequately supported against sway and out-of-plane buckling, by bracings, moment resisting frame or an independent system such as shear wall.

11.5.2.4 Fabrication restriction

Within a length equal to the member depth, on either side of a plastic hinge location, the following restrictions should be applied to the tension flange and noted in the design drawings. Holes, if required, should be drilled or else punched 2 mm undersize and

reamed. All sheared or hand flame cut edges should be finished smooth by grinding, chipping or planning.

11.5.3 Assumptions in Analysis

The design action effects shall be determined using a rigid-plastic analysis.

It shall be permissible to assume full strength or partial strength connections, provided the capacities of these are used in the analysis, and provided that,

- a) In a full strength connection, the moment capacity of the connection shall be not less than that of the member being connected;
- b) In a partial strength connection, the moment capacity of the connection may be less than that of the member being connected; and
- c) In both cases the behavior of the connection shall be such as to allow all plastic hinges necessary for the collapse mechanism to develop, and shall be such that the required plastic hinge rotation does not exceed the rotation capacity at any of the plastic hinges in the collapse mechanism.

In the case of building structures, it is not normally necessary to consider the effect of alternating plasticity.

11.6 Frame Buckling Analysis

11.6.1 The elastic buckling load factor (λ_{cr}) shall be the ratio of the elastic buckling load set of the frame to the design load set for the frame, and shall be determined in accordance with **11.6.2**.

NOTE – The value of λ_{cr} depends on the load set and has to be evaluated for each possible set of load combination.

11.6.2 In-plane frame buckling

The elastic buckling load factor (λ_{cr}) of a rigid-jointed frame shall be determined by using:

- a) One of the approximate methods of **11.6.2.1** and **11.6.2.2**, or
- b) A rational elastic buckling analysis of the whole frame.

11.6.2.1 Regular non-sway frames (see 11.1.2)

In a rectangular non-sway frame with regular loading and negligible axial forces in the beams, the Euler buckling stress f_{cc} , for each column shall be determined in accordance with **14.1.2.1**. The elastic buckling load factor (λ_{cr}) for the whole frame shall be taken as the lowest of the ratio of (f_{cc}/f_{cd}) for all the columns, where f_{cd} is the axial compressive stress in the column from the factored load analysis.

11.6.2.2 Regular sway frames

In a rectangular sway frame with regular loading and negligible axial forces in the beams, the buckling load, P_{cc} , for each column shall be determined as $P_{cc} = A f_{cc}$ where f_{cc} is the

elastic buckling stress of the column in the plane of frame, obtained in accordance with **14.1.2.1**. The elastic buckling load factor λ_{cr} , for the whole frame shall be taken as the lowest of all the ratios, λ_{scr} , calculated for each storey of the building, as given below:

$$\lambda_{scr} = \frac{\sum (P_{cc} / L)}{\sum (P / L)}$$

where

P = member axial force from the factored load analysis, with tension taken as negative, and
 L = column length and the summation includes all columns in the plane frame within a storey.

11.7 Consideration of Second Order Effects

11.7.1 Any second-order effects of the loads acting on the structure in its deformed configuration may be neglected and first order elastic analysis or plastic analysis results may be used provided the following are satisfied:

- a) For clad frames, provided with the stiffening effects of masonry infill wall panels or diaphragms of profiled wall panel is not taken into account, and where elastic buckling load factor, λ_{cr} (see **11.6**) satisfies $\lambda_{cr}/\lambda_u \geq 10$.

If $10 > \lambda_{cr}/\lambda_u \geq 4.6$ the second-order effects may be considered by amplifying the design load effects obtained from elastic/plastic analysis by a factor as given in **11.7.3.1**

If $\lambda_{cr}/\lambda_u < 4.6$, second-order elastic analysis or second-order plastic analysis (see **11.7.3**) is to be carried out.

- b) for un-clad frames or for clad frames where the stiffening effects of masonry infill or diaphragms of profiled wall panel is taken into account, where elastic buckling load factor, λ_{cr} (see **11.6**) satisfies $\lambda_{cr}/\lambda_u \geq 20$

If $20 > \lambda_{cr}/\lambda_u \geq 5.75$ the second-order effects may be considered by amplifying the design load effects obtained from plastic analysis by a factor as given in **11.7.3.2**

If $\lambda_{cr}/\lambda_u < 5.75$, second-order elasto-plastic analysis or second-order elastic analysis (see **11.7.2**) shall be carried out.

Where λ_u - Ultimate load factor from elastic or plastic analysis

11.7.2 Second-order Elastic Analysis

11.7.2.1 The analysis shall allow for the effects of the design loads acting on the structure and its members in their displaced and deformed configuration. These second-order effects shall be taken into account by using either:

- a) A first-order elastic analysis with moment amplification in accordance with **11.7.3.1**, **11.7.3.2**, provided the moment amplification factors, K_y and K_z are not greater than 1.4; or
- b) A second-order elastic analysis in accordance with Annex B.

11.7.3 Moment Amplification

11.7.3.1 *Moment amplification for members in non-sway frames*

For a member with zero axial compression or a member subject to axial tension, the design bending moment is that obtained from the first-order analysis for factored loads, without any amplification.

For a braced member with a design axial compressive force P_d as determined by the first-order analysis, the design bending moment shall be calculated considering moment amplification as in **16.3.2.2**.

11.7.3.2 *Moment amplification for members in sway frames*

The design bending moment shall be calculated as the product of moment amplification factor, [see **16.3.2.2** (K_y , K_z)] and the moment obtained from the first-order analysis of the sway frame, unless analysis considering second order effects is carried out (see **11.7.2**).

11.7.4 The calculated bending moments from the first order elastic analysis may be modified by redistribution up to 15 percent of the peak calculated moment of the member under factored load, provided that,

- a) the internal forces and moments in the members of the frame are in equilibrium with applied loads.
- b) all the members in which the moments are reduced shall belong to plastic or compact section classification (see **10.7**).

12 LIMIT STATE DESIGN

12.1 Basis for Design

12.1.1 In the limit state design method, the structure shall be designed to withstand safely all loads likely to act on it throughout its life. It shall not suffer total collapse under accidental loads such as from explosions or impact or due to consequences of human error to an extent beyond the local damages. The objective of the design is to achieve a structure that will remain fit for use during its life with acceptable target reliability. In other words, the probability of a limit state being reached during its lifetime should be very low. The acceptable limit for the safety and serviceability requirements before failure occurs is called a limit state. In general, the structure shall be designed on the basis of the most critical limit state and shall be checked for other limit states.

12.1.2 Steel structures are to be designed and constructed to satisfy the design requirements with regard to stability, strength, serviceability, brittle fracture, fatigue, fire, and durability such that they meet the following:

- a) Remain fit with adequate reliability and be able to sustain all actions (loads) and other influences experienced during construction and use;
- b) Have adequate durability under normal maintenance;
- c) Do not suffer overall damage or collapse disproportionately under accidental events like explosions, vehicle impact or due to consequences of human error to an extent beyond local damage. The potential for catastrophic damage shall be limited or avoided by appropriate choice of one or more of the following:
 - 1) Avoiding, eliminating or reducing exposure to hazards, which the structure is likely to sustain.
 - 2) Choosing structural forms, layouts and details and designing such that,
 - i) the structure has low sensitivity to hazardous conditions; and
 - ii) the structure survives with only local damage even after serious damage to any one individual element by the hazard;
 - 3) Choosing suitable material, design and detailing procedure, construction specifications, and control procedures for shop fabrication and field construction as relevant to the particular structure.

The following conditions may be satisfied to avoid a disproportionate collapse:

- a) The building should be effectively tied together at each principal floor level and each column should be effectively held in position by means of continuous ties (beams) nearly orthogonal, except where the steel work supports only cladding weighing not more than 0.7 kN/m^2 along with imposed and wind loads. These ties must be steel members such as beams, which may be designed for other purposes, steel bar reinforcement anchoring the steel frame to concrete floor or steel mesh reinforcement in composite slab with steel profiled sheeting directly connected to beam with shear connectors. These steel ties and their end connections should be capable of resisting factored tensile force not less than the factored dead and imposed loads acting on the floor area tributary to the tie nor less than 75 kN. Such connection of ties to edge column should also be capable of resisting 1 percent of the maximum axial compression in the column at the level due to factored dead and imposed loads. All column splices should be capable of resisting a tensile force equal to the largest of a factored dead and imposed load reaction from a single floor level located between that column splice and the next column splice below that splice. Lateral load system to resist notional horizontal loads prescribed in **11.3.6** should be distributed throughout the building in nearly orthogonal directions so that no substantial portions is connected at only one point to such a system. Precast concrete or other heavy floor or roof units should be effectively anchored in the direction of their span either to each other over the support or directly to the support.
- b) Where the above conditions to tie the columns to the floor adequately are not satisfied each storey of the building should be checked to ensure that

disproportionate collapse would not precipitate by the notional removal, one at a time, of each column.

- c) Where each floor is not laterally supported by more than one system, check should be made at each storey by removing one such lateral support system at a time to ensure that disproportionate collapse would not occur. The collapse is considered disproportionate, if more than 15 percent of the floor or roof area of 70 m² collapse at that level and at one adjoining level either above or below it, under a load equal to 1.05 or 0.9 times the dead load, 0.33 times temporary or full imposed load of permanent nature (as in storage buildings) and 0.33 times wind load acting together.

12.1.3 Structures designed for unusual or special functions shall comply with any other relevant additional limit state considered appropriate to that structure.

12.2 Limit State Design

12.2.1 For achieving the design objectives, the design shall be based on characteristic values for material strengths and applied loads (actions), which take into account the probability of variations in the material strengths and in the loads to be supported. The characteristic values shall be based on statistical data, if available. Where such data is not available, these shall be based on experience. The design values are derived from the characteristic values through the use of partial safety factors, both for material strengths and for loads. In the absence of special considerations, these factors shall have the values given in this Section according to the material, the type of load and the limit state being considered. The reliability of design is ensured by satisfying the requirement:

$$\text{Design action} \leq \text{Design strength}$$

12.2.2 Limit states are the states beyond which the structure no longer satisfies the performance requirements specified. The limit states are classified as:

- a) Limit state of strength; and
- b) Limit state of serviceability.

12.2.2.1 The limit states of strength are those associated with failures (or imminent failure), under the action of probable and most unfavourable combination of loads on the structure using the appropriate partial safety factors, which may endanger the safety of life and property. The limit state of strength includes,

- a) loss of equilibrium of the structure as a whole or any of its parts or components.
- b) loss of stability of the structure (including the effect of sway where appropriate and overturning) or any of its parts including supports and foundations.
- c) failure by excessive deformation, rupture of the structure or any of its parts or components.
- d) fracture due to fatigue.
- e) brittle fracture.

12.2.2.2 The limit state of serviceability include,

- a) deformation and deflections, which may adversely affect the appearance or effective use of the structure or may cause improper functioning of equipment or services or may cause damages to finishes and non-structural members.
- b) vibrations in the structure or any of its components causing discomfort to people, damages to the structure, its contents or which may limit its functional effectiveness. Special consideration shall be given to systems susceptible to vibration, such as large open floor areas free of partitions to ensure that such vibrations are acceptable for the intended use and occupancy (see Annex C).
- c) repairable damage or crack due to fatigue.
- d) corrosion, durability, and
- e) fire.

12.3 Actions

The actions (loads) to be considered in design include direct actions (loads) experienced by the structure due to self weight, external actions, etc, and imposed deformations such as that due to temperature and settlements.

12.3.1 Classification of Actions

Actions are classified by their variation with time as given below:

- a) *Permanent actions* (Q_p) – Actions due to self-weight of structural and non-structural components, fittings, ancillaries, and fixed equipment, etc.
- b) *Variable actions* (Q_v) – Actions due to construction and service stage loads such as imposed (live) loads (crane loads, snow loads, etc.), wind loads, and earthquake effects.
- c) *Accidental actions* (Q_a) – Actions expected due to explosions, and impact of vehicles, etc.

12.3.2 Characteristic Actions (Loads)

12.3.2.1 The characteristic actions, Q_c , are the values of the different actions that are not expected to be exceeded with more than 5 percent probability, during the life of the structure and they are taken as,

- a) the self-weight, in most cases calculated on the basis of nominal dimensions and unit weights [see 2 of Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code].
- b) the variable loads, values of which are specified in relevant standard (see Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code).
- c) the upper limit with a specified probability (usually 5 percent) not exceeding during some reference period (design life).
- d) specified by client, or by designer in consultation with client, provided they satisfy the minimum provisions of the relevant loading standard.

12.3.2.2 The characteristic values of accidental loads generally correspond to the value specified by relevant code, standard or client. The design for accidental load is

generally not required in building unless it is required by client or approving authority in which case, generally recommendation in **12.1.2 c)** or specialist literature shall be followed.

12.3.3 Design Actions

The design action, Q_d , is expressed as $Q_d = \sum_k \gamma_{fk} Q_{ck}$

where

γ_{fk} = partial safety factor for different loads k , given in Table 4 to account for,

- a) possibility of unfavourable deviation of the load from the characteristic value,
- b) possibility of inaccurate assessment of the load,
- c) uncertainty in the assessment of effects of the load, and
- d) uncertainty in the assessment of the limit states being considered.

The loads or load effects shall be multiplied by the relevant γ_f factors, given in Table 4, to get the design loads or design load effects.

12.4 Strength

The ultimate strength calculation may require consideration of the following:

- a) Loss of equilibrium of the structure or any part of it, considered as a rigid body, and
- b) Failure by excessive deformation, rupture or loss of stability of the structure or any part of it including support and foundation.

12.4.1 Design Strength

The design strength, S_d , is obtained as given below from ultimate strength, S_u and partial safety factors for materials, γ_m given in Table 5.

$$S_d = S_u / \gamma_m$$

where partial safety factor for materials, γ_m account for,

- a) possibility of unfavourable deviation of material strength from the characteristic value;
- b) possibility of unfavourable variation of member sizes;
- c) possibility of unfavourable reduction in member strength due to fabrication and tolerances; and
- d) uncertainty in the calculation of strength of the members.

Table 4 Partial Safety Factors for Loads, γ_f , for Limit States
(Clauses 10.5.1 and 12.3.3)

SI No.	Combination	Limit State of Strength						Limit State of Serviceability			
		DL	IL ¹⁾		WL/EL	FL	AL	DL	IL ¹⁾		WL/EL
			Leading	Accompanying					Leading	Accompanying

ii)	DL+IL+CL+ WL/EL	1.2 1.2	1.2 1.2	1.05 0.53	0.6 1.2	—	—	1.0	0.8	0.8	0.8
iii)	DL+WL/EL	1.5 (0.9) ²⁾	—	—	1.5	—	—	1.0	—	—	1.0
iv)	DL+ER	1.2 (0.9) ²⁾	1.2	—	—	—	—	—	—	—	—
v)	DL+IL ³⁾ +FL	1.0	1.0/0.5	—	—	1.0	—	—	—	—	—
v)	DL+IL+AL	1.0	0.35	0.35	—	—	1.0	—	—	—	—

¹⁾ When action of different imposed loads is simultaneously considered, the leading imposed load shall be considered to be the one causing the higher load effects in the member/section.

²⁾ This value is to be considered when the dead load contributes to stability against overturning is critical or the dead load causes reduction in stress due to other loads.

³⁾ Imposed load shall be taken as the full characteristic specified values in case of storage loads and 50 percent of the specified characteristic values in other cases.

Abbreviations:

DL= Dead load, IL= Imposed load, WL= Wind load, CL= Crane load (Vertical/Horizontal), AL=Accidental load, ER= Erection load, EL= Earthquake effects, FL = Forces due to restraints during fire.

NOTE – The effects of actions (loads) in terms of stresses or stress resultants may be obtained from an appropriate method of analysis as in 11.

Table 5 Partial Safety Factor for Materials, γ_m
(Clause 12.4.1)

SI No.	Definition	Partial Safety Factor

	d) Welds, γ_{mw}	1.25	1.50

12.5 Factors Governing the Ultimate Strength

12.5.1 Stability

Stability shall be ensured for the structure as a whole and for each of its elements. This should include, overall frame stability against overturning and sway, as given in **12.5.1.1** and **12.5.1.2**.

12.5.1.1 Stability against overturning

The structure as a whole or any part of it shall be designed to prevent instability due to overturning, uplift or sliding under factored load as given below:

- The actions shall be divided into components aiding instability and components resisting instability.
- The permanent and variable actions and their effects causing instability shall be combined using appropriate partial safety factors for loads as per the limit state requirements, to obtain maximum destabilizing effect.
- The permanent actions (loads) and effects contributing to resistance shall be multiplied with a partial safety factor 0.9 and added together with design resistance (after multiplying with appropriate partial safety factor). Variable actions and their effects contributing to resistance shall be disregarded.
- The resistance effect shall be greater than or equal to the destabilizing effect. Combination of imposed and dead loads should be such as to cause most severe effect on overall stability.

12.5.1.2 Sway stability

The whole structure, including portions between expansion joints, shall be adequately stiff against sway. To ensure this, in addition to designing for applied horizontal loads, a separate check should be carried out for notional horizontal loads such as given in **11.3.6** to evaluate the sway under gravity loads.

12.5.2 Fatigue

Generally, fatigue need not be considered unless a structure or element is subjected to numerous significant fluctuations of stress. Stress changes due to fluctuations in wind loading normally need not be considered. Fatigue design shall be in accordance with the provisions under **19**. When designing for fatigue, the partial safety factor for load, γ_L , equal to unity shall be used for the load causing stress fluctuation and stress range.

12.5.3 Plastic Collapse

Plastic analysis and design may be used, if the requirement specified under the plastic method of analysis (see **11.5**) are satisfied.

12.6 Limit State of Serviceability

Serviceability limit state is related to the criteria governing normal use. Serviceability limit state is limit state beyond which the service criteria specified below, are no longer met:

- a) Deflection limit,
- b) Vibration limit,
- c) Durability consideration, and
- d) Fire resistance.

Unless specified otherwise (see Table 4), partial safety factor for loads, γ_L , of value equal to unity shall be used for all loads leading to serviceability limit states to check the adequacy of the structure under serviceability limit states.

12.6.1 Deflection

The deflection under serviceability loads of a building or a building component should not impair the strength of the structure or components or cause damage to finishing. Deflections are to be checked for the most adverse but realistic combination of service loads and their arrangement, by elastic analysis, using partial safety factors in Table 4 for loads, as required, in Table 6. Table 6 gives recommended limits of deflections for certain structural members and systems. In Table 6, imposed load should include all post construction loads including superimposed dead loads. Circumstances may arise where greater or lesser values would be more appropriate, depending upon the nature of material in element to be supported (vulnerable to cracking or not) and intended use of the structure, as required by client.

12.6.1.1 Where the deflection due to the combination of dead load and imposed load is likely to be excessive, consideration should be given to pre-camber the beams, trusses and girders. The value of desired camber shall be specified in design drawing. Generally, for spans greater than 25 m, a camber approximately equal to the deflection due to dead loads plus half the imposed load may be used. The deflection of a member shall be calculated without considering the impact factor or dynamic effect of the loads on deflection. Roofs, which are very flexible, shall be designed to withstand any additional load that is likely to occur as a result of ponding of water or accumulation of snow or ice.

12.6.2 Vibration

Suitable provisions in the design shall be made for the dynamic effects of imposed loads, impact loads and vibration due to machinery operating loads. In severe cases possibility of resonance, fatigue or unacceptable vibrations shall be investigated. Unusually flexible structures (generally the height to effective width of lateral load resistance system exceeding 5:1) shall be investigated for lateral vibration under dynamic wind loads. Structures subjected to large number of cycles of loading shall be designed against fatigue failure, as specified under **19**. Floor vibration effect shall be considered using specialist literature (see Annex C).

12.6.3 Durability

Factors that affect the durability of the buildings, under conditions relevant to their intended life, are listed below:

- a) Environment,
- b) Degree of exposure,
- c) Shape of the member and the structural detail,
- d) Protective measure, and
- e) Ease of maintenance.

12.6.3.1 The durability of steel structures shall be ensured by following recommendations given under **21**. Specialist literature may be referred to for more detailed and additional information in design for durability.

12.6.4 Fire Resistance

Fire resistance of a steel member is a function of its mass, its geometry, and the actions to which it is subjected, its structural support condition, fire protection measures adopted and the fire to which it is exposed. Design provisions to resist fire are briefly discussed under **22**. Specialist literature may be referred to for more detailed information in design of fire resistance of steel structures.

13 DESIGN OF TENSION MEMBERS

13.1 Tension Members

Tension members are linear members in which axial forces act to cause elongation (stretch). Such members can sustain loads up to the ultimate load, at which stage they may fail by rupture at a critical section. However, if the gross area of the member yields over a major portion of its length before the rupture load is reached, the member may become non-functional due to excessive elongation. Plates and other rolled sections in tension may also fail by block shear of end bolted regions (see **13.4.1**).

The factored design tension T , in the members shall satisfy the following requirement:

$$T < T_d$$

where

T_d = Design strength of the member.

The design strength of a member under axial tension, T_d , is the lowest of the design strength due to yielding of gross section, T_{dg} ; rupture strength of critical section, T_{dn} ; and block shear T_{db} , given in **13.2**, **13.3** and **13.4**, respectively.

13.2 Design Strength Due to Yielding of Gross Section

The design strength of members under axial tension, T_{dg} , as governed by yielding of gross section, is given by:

$$T_{dg} = A_g f_y / \gamma_{m0}$$

where

f_y = yield stress of the material,

A_g = gross area of cross section, and

γ_{m0} = partial safety factor for failure in tension by yielding (see Table 5).

13.3 Design Strength Due to Rupture of Critical Section

13.3.1 Plates

The design strength in tension of a plate, T_{dn} , as governed by rupture of net cross sectional area, A_n , at the holes is given by

$$T_{dn} = 0.9 A_n f_u / \gamma_{m1}$$

where

γ_{m1} = partial safety factor for failure at ultimate stress (see Table 5),

f_u = ultimate stress of the material, and

A_n = net effective area of the member given by.

$$A_n = \left[b - n d_h + \sum \frac{p_{si}^2}{4g_i} \right] t$$

where

b, t = width and thickness of the plate, respectively,

d_h = diameter of the bolt hole (2 mm in addition to the diameter of the hole, in case of directly punched holes),

g = gauge length between the bolt holes, as shown in Fig. 5,

p_s = staggered pitch length between line of bolt holes, as shown in Fig. 5,

n = number of bolt holes in the critical section, and

i = subscript for summation of all the inclined legs.

$$p_s$$

FIG. 5 PLATES WITH BOLTS HOLES IN TENSION

13.3.2 Threaded Rods

The design strength of threaded rods in tension, T_{dn} , as governed by rupture is given by:

$$T_{dn} = 0.9 A_n f_u / \gamma_{m1}$$

where

A_n = net root area at the threaded section.

13.3.3 Single Angles

The rupture strength of an angle connected through one leg is affected by shear lag. The design strength, T_{dn} , as governed by rupture at net section is given by:

$$T_{dn} = 0.9 A_{nc} f_u / \gamma_{m1} + \beta A_{go} f_y / \gamma_{m0}$$

where

$$\beta = 1.4 - 0.076 (w/t) (f_y/f_u) (b_s/L_c) \leq (0.9 f_u \gamma_{m0} / f_y \gamma_{m1})$$

$$\geq 0.7$$

where

w = outstand leg width,

b_s = shear lag width, as shown in Fig. 6, and

L_c = length of the end connection, that is the distance between the outermost bolts in the end joint measured along the load direction or length of the weld along the load direction.

A_n = net area of the total cross section,

A_{nc} = net area of the connected leg,

A_{go} = gross area of the outstanding leg, and
 t = thickness of the leg.

FIG. 6 ANGLES WITH SINGLE LEG CONNECTIONS

13.3.4 Other Section

The rupture strength, T_{dn} , of the double angles, channels, I-sections and other rolled steel sections, connected by one or more elements to an end gusset is also governed by shear lag effects. The design tensile strength of such sections as governed by tearing of net section may also be calculated using equation in **13.3.3**, where β is calculated based on the shear lag distance, b_s , taken from the farthest edge of the outstanding leg to the nearest bolt/weld line in the connected leg of the cross section.

13.4 Design Strength Due to Block Shear

The strength as governed by block shear at an end connection of plates and angles is calculated as given in **13.4.1**.

13.4.1 Bolted Connections

The block shear strength, T_{db} of connection shall be taken as the smaller of,

$$T_{db} = [A_{vg} f_y / (\sqrt{3} \gamma_{m0}) + 0.9 A_{tn} f_u / \gamma_{m1}]$$

or

$$T_{db} = [0.9 A_{vn} f_u / (\sqrt{3} \gamma_{m1}) + A_{tg} f_y / \gamma_{m0}]$$

where

A_{vg} , A_{vn} = minimum gross and net area in shear along bolt line parallel to external force, respectively (1-2 and 3-4 as shown in Fig. 7a and 1-2 as shown in Fig. 7b),

A_{tg} , A_{tn} = minimum gross and net area in tension from the bolt hole to the toe of the angle, end bolt line, perpendicular to the line of force, respectively (2-3 as shown in Fig. 7b), and

f_u , f_y = ultimate and yield stress of the material, respectively.

FIG. 7 BLOCK SHEAR FAILURE

13.4.2 Welded Connection

The block shear strength, T_{db} shall be checked for welded end connections by taking an appropriate section in the member around the end weld, which can shear off as a block.

14 DESIGN OF COMPRESSION MEMBERS

14.1 Design Strength

14.1.1 Common hot rolled and built-up steel members used for carrying axial compression, usually fail by flexural buckling. The buckling strength of these members is affected by residual stresses, initial bow and accidental eccentricities of load. To account for all these factors, the strength of members subjected to axial compression is defined by buckling class a_0 , a , b , c , or d as given Table 7.

14.1.2 The factored design compression, P in members shall satisfy the following requirement:

$$P < P_d$$

where

$$P_d = A_e f_{cd}$$

where

A_e = effective sectional area as defined in **14.3.2**, and

f_{cd} = design compressive stress, given by.

$$f_{cd} = \frac{\chi f_y}{\gamma_{m0}} \leq f_y / \gamma_{m0}$$

where

χ = stress reduction factor for different buckling class, slenderness ratio and yield stress and mode of buckling as given in **14.1.2.1** or **14.1.2.2**, as applicable (see Table 8)

γ_{m0} = partial safety factor for material strength.

14.1.2.1 Reduction Factor for flexural buckling

$$\chi = \frac{1}{\phi + \sqrt{\phi^2 + \lambda^2}}$$

$$\phi = 0.5[1 + \alpha(\lambda - 0.2) + \lambda^2]$$

λ = non-dimensional effective slenderness ratio

$$= \sqrt{f_y / f_{cr}} = \sqrt{f_y \left(\frac{KL}{r} \right)^2 / \pi^2 E}$$

$$f_{cr} = \text{Euler buckling stress about the relevant axis} = \frac{\pi^2 E}{(KL/r)^2}$$

where

KL/r = effective slenderness ratio or ratio of effective length, KL to appropriate radius of gyration, r ;

α = imperfection factor given in Table 7;

14.1.2.2 Reduction Factor for Torsional and Torsional Flexural Buckling

$$\chi = \frac{1}{\phi + \sqrt{\phi^2 + \lambda_{TF}^2}}$$

$$\phi = 0.5 \left[1 + \left(\frac{\lambda_{TF}}{\lambda_y} \right)^2 \cdot \alpha_{TF} (\lambda_y - 0.2) + \lambda_{TF}^2 \right]$$

$$\alpha_{TF} = \alpha \sqrt{\frac{A f_y (i_p^2 + d_y^2)}{6.25 G I_T}}$$

where

α is the imperfection factor given in table 7

i_p is the polar radius of gyration given by

$$i_p^2 = (I_y + I_z)/A$$

λ_y is the distance between intermediate lateral support and shear centre

λ_{TF} = non-dimensional effective slenderness ratio

$$= \sqrt{f_y / f_{crTF}}$$

f_{crTF} = Torsional buckling stress

NOTE – Calculated values of design compressive stress, f_{cd} for different buckling classes are given in Table 9.

14.1.2.3 The classification of different sections under different buckling class a_0 , a , b , c or d , is given in Table 10. The stress reduction factor χ , and the design compressive stress f_{cd} , for different buckling class, yield stress, and effective slenderness ratio is given in Table 8 for convenience. The curves corresponding to different buckling class are presented in non-dimensional form, in Fig. 8.

Table 7 Imperfection Factor, α
(Clauses 14.1.1 and 14.1.2)

Buckling Class	a_0	a	b	c	d
(1)	(2)	(3)	(4)	(5)	(6)
α	0.13	0.21	0.34	0.49	0.76

FIG. 8 BUCKLING CURVES

14.2 Effective Length of Compression Members

14.2.1 The effective length KL , is calculated from the actual length L , of the member, considering the rotational and relative translational boundary conditions at the ends. The actual length shall be taken as the length from center to center of its intersections with the supporting members in the plane of the buckling deformation. In the case of a member with a free end, the free standing length from the center of the intersecting member at the supported end, shall be taken as the actual length.

14.2.2 Effective Length

Where the boundary conditions in the plane of buckling can be assessed, the effective length, KL can be calculated on the basis of Table 11. Where frame analysis does not consider the equilibrium of a framed structure in the deformed shape (second-order analysis or advanced analysis), the effective length of compression members in such cases can be calculated using the procedure given in **C-1**. The effective length of stepped column in single storey buildings can be calculated using the procedure given in **C-2**.

14.2.3 Eccentric Beam Connection

In cases where the beam connections are eccentric in plan with respect to the axes of the column, the same conditions of restraint as in concentric connection shall be deemed to apply, provided the connections are carried across the flange or web of the

columns as the case may be, and the web of the beam lies within, or in direct contact with the column section. Where practical difficulties prevent this, the effective length shall be taken as equal to the distance between points of restraint in non-sway frames.

14.2.4 Compression Members in Trusses

In the case of bolted, riveted or welded trusses and braced frames, the effective length, KL , of the compression members shall be taken as 0.7 to 1.0 times the distance between centers of connections, depending on the degree of end restraint provided. In the case of members of trusses buckling in the plane perpendicular to the plane of the truss, the effective length, KL shall be taken as the distance between the centers of intersection. The design of angle struts shall be as specified in **14.5**.

14.3 Design Details

14.3.1 Thickness of Plate Elements

Classification of members on the basis of the thickness of constituent plate elements shall satisfy the width-thickness ratio requirements specified in Table 2.

14.3.2 Effective Sectional Area, A_e

Except as modified in **10.7.2** (Class 4), the gross sectional area shall be taken as the effective sectional area for all compression members fabricated by welding, bolting and riveting so long as the section is semi-compact or better. Holes not fitted with rivets, bolts or pins shall be deducted from gross area to calculate effective sectional area.

14.3.3 Eccentricity for Stanchions and Columns

14.3.3.1 For the purpose of determining the stress in a stanchion or column section, the beam reactions or similar loads shall be assumed to be applied at an eccentricity of 100 mm from the face of the section or at the center of bearing whichever dimension gives the greater eccentricity, and with the exception of the following two cases:

- a) In the case of cap connection, the load shall be assumed to be applied at the face of the column or stanchion section or at the edge of packing, if used towards the span of the beam.
- b) In the case of a roof truss bearing on a cap, no eccentricity be taken for simple bearings without connections capable of developing any appreciable moment. In case of web member connection with face, actual eccentricity is to be considered.

Table 10 Buckling Class of Cross Sections
(Clause 14.1.2.2)

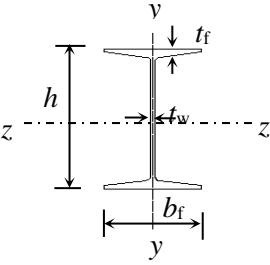

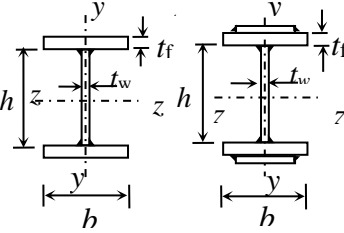

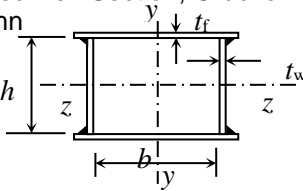

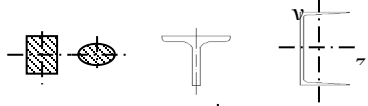

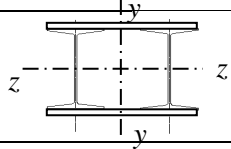

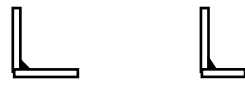

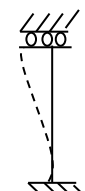

Cross section (1)	Limits (2)	Buckling About Axis (3)	Buckling Class	
			$f_y \leq 420$ MPa	$f_y > 420$ MPa
			(4)	(5)
Rolled I-Sections 	$h/b_f > 1.2$: $t_f \leq 40$ mm	z-z y-y	a b	a ₀ a
	$40\text{mm} < t_f \leq 100$ mm	z-z y-y	b c	a b
	$h/b_f \leq 1.2$: $t_f \leq 100$ mm	z-z y-y	b c	a b
	$t_f > 100$ mm	z-z y-y	d d	c c
Welded I-Section 	$t_f \leq 40$ mm	z-z y-y	b c	b c
	$t_f > 40$ mm	z-z y-y	c d	c d
Hollow Section 	Hot rolled	any	a	a ₀
	Cold formed	any	b	c
Welded Box Section, Cruciform column 	Generally (except as below)	any	b	b
	Thick welds $b/t_f < 30$	z-z	c	c
	$h/t_w < 30$	y-y	c	c
Channel, Angle, T, and Solid Sections 		any	c	c
Built-up Member 		any	c	c
Rolled Sections 		any	b	a
Welded sections $t \leq 40$ mm 		any	c	c

Table 11 Effective Length of Prismatic Compression Members
(Clause 14.2.2)

Boundary Conditions				Schematic Representation	Effective Length
At One End		At the Other End			
Translation (1)	Rotation (2)	Translation (3)	Rotation (4)		
(1)	(2)	(3)	(4)	(5)	(6)
Restrained	Restrained	Free	Free		2.0L
Restrained	Free	Free	Restrained		
Restrained	Free	Restrained	Free		1.0L
Restrained	Restrained	Free	Restrained		1.2L
Restrained	Restrained	Restrained	Free		0.8L
Restrained	Restrained	Restrained	Restrained		0.65L

NOTE – L is the unsupported length of the compression member (see 13.2.1).

14.3.3.2 In continuous columns, the bending moments due to eccentricities of loading on the columns at any floor may be divided equally between the columns above and below that floor level, provided that the moment of inertia of one column section, divided by its effective length does not exceed 1.5 times the corresponding value of the other column. Where this ratio is exceeded, the bending moment shall be divided in proportion to the moment of inertia of the column sections divided by their respective effective lengths.

14.3.4 Splices

14.3.4.1 Where the ends of compression members are prepared for bearing over the whole area, they shall be spliced to hold the connected members accurately in position, and to resist bending or tension, if present. Such splices should maintain the intended member stiffness about each axis. Splices should be located as close to the point of inflection as possible. Otherwise their capacity should be adequate to carry magnified moment (see **16.3.2.2**). The ends of compression members faced for bearing shall invariably be machined to ensure perfect contact of surfaces in bearing.

14.3.4.2 Where such members are not faced for complete bearing, the splices shall be designed to transmit all the forces to which the members are subjected.

14.3.4.3 Wherever possible, splices shall be proportioned and arranged so that the centroidal axis of the splice coincides as nearly as possible with the centroidal axes of the members being jointed, in order to avoid eccentricity; but where eccentricity is present in the joint, the resulting stress shall be accounted for.

14.4 Column Bases

14.4.1 General

Column bases should have sufficient stiffness and strength to transmit axial force, bending moments and shear forces at the base of the columns to their foundation without exceeding the load carrying capacity of the supports. Anchor bolts and shear keys should be provided wherever necessary. Shear resistance at the proper contact surface between steel base and concrete/grout may be calculated using a friction coefficient of 0.45.

The nominal bearing pressure between the base plate and the support below may be determined on the basis of linearly varying distribution of pressure. The maximum bearing pressure on concrete under the limit states design load should not exceed the bearing strength equal to $0.45f_{ck} [\sqrt{A_1/A_2}]$ and $0.9f_{ck}$, whichever is smaller, where f_{ck} is the smaller of characteristic cube strength of concrete or bedding material, A_1 is the area of concrete pedestal on which the base plate is sitting, and A_2 is the surface area of the steel base plate transferring the load to the concrete pedestal.

14.4.1.1 If the size of the base plate is larger than that required to limit the bearing pressure on the base support, an equal projection c of the base plate beyond the face of

the column and gusset may be taken as effective in transferring the column load as given in Fig. 9, such that bearing pressure on the effective area does not exceed bearing capacity of concrete base.

14.4.2 Gusseted Bases

For stanchion with gusseted bases, the gusset plates, angle cleats, stiffeners, fastenings, etc, in combination with the bearing area of the shaft, shall be sufficient to take the loads, bending moments and reactions to the base plate without exceeding specified strength. All the bearing surfaces shall be machined to ensure perfect contact.

14.4.2.1 Where the ends of the column shaft and the gusset plates are not faced for complete bearing, the welds, fastenings connecting them to the base plate shall be sufficient to transmit all the forces to which the base is subjected.

14.4.2.2 Column and base plate connections

Where the end of the column is connected directly to the base plate by means of full penetration butt welds, the connection shall be deemed to transmit to the base all the forces and moments to which the column is subjected.

14.4.3 Slab Bases

Columns with slab bases need not be provided with gussets, but sufficient fastenings shall be provided to retain the parts securely in place and to resist all moments and forces, other than direct compression, including those arising during transit, unloading and erection.

14.4.3.1 The minimum thickness, t_s , of rectangular slab bases, supporting columns under axial compression shall be

$$t_s = \sqrt{2.5 w (a^2 - 0.3b^2) \gamma_{m0} / f_y} > t_f$$

where

w = uniform pressure from below on the slab base under the factored load axial compression;

a, b = larger and smaller projection, respectively of the slab base beyond the rectangle circumscribing the column; and

t_f = flange thickness of compression member.

When only the effective area of the base plate is used as in **14.4.1.1**, c^2 may be used in the above equation (see Fig. 9) instead of $(a^2 - 0.3b^2)$.

14.4.3.2 When the slab does not distribute the column load uniformly, due to eccentricity of the load etc, special calculation shall be made to show that the base is adequate to resist the moment due to the non-uniform pressure from below.

14.4.3.3 Bases for bearing upon concrete or masonry need not be machined on the underside.

14.4.3.4 In cases where the cap or base is fillet welded directly to the end of the column without boring and shouldering, the contact surfaces shall be machined to give a perfect bearing and the welding shall be sufficient to transmit the forces as required in **14.4.3**. Where full strength butt welds are provided, machining of contact surfaces is not required.

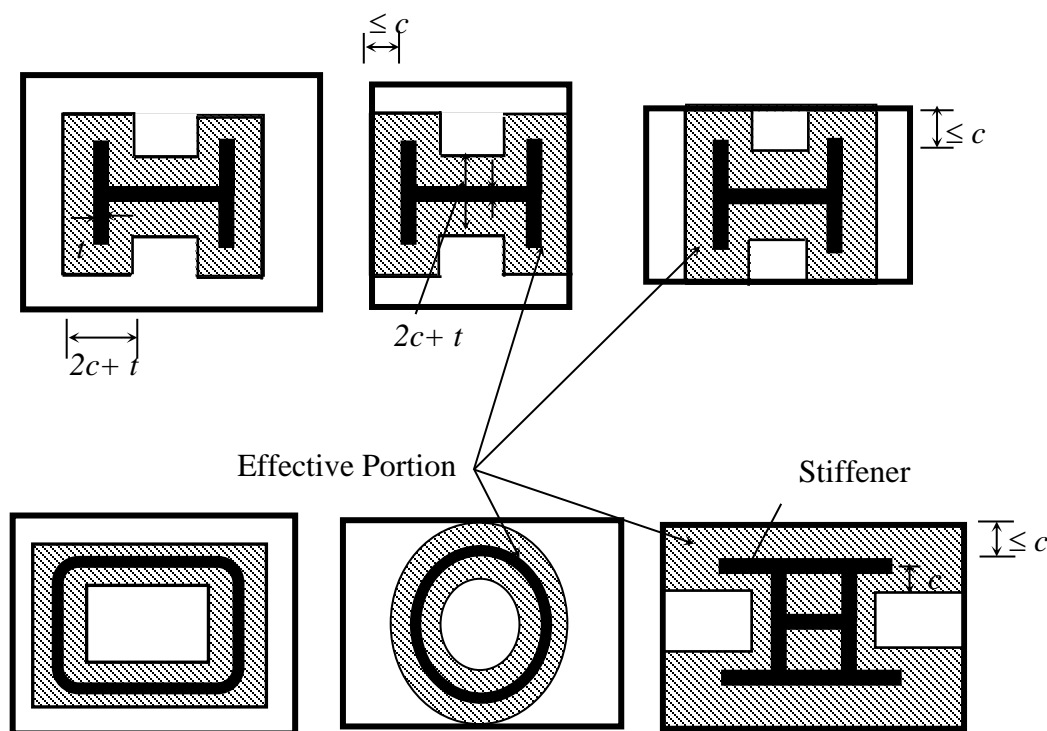

FIG. 9 EFFECTIVE AREA OF A BASE PLATE

14.5 Angle Struts

14.5.1 Single Angle Struts

The compression in single angles may be transferred either concentrically to its centroid through the end connections or eccentrically by connecting one of its legs to a gusset or adjacent member.

14.5.1.1 Concentric loading

When a single angle is concentrically loaded in compression, the design strength may be evaluated using **14.1.2**, by calculating the non-dimensional slenderness ratio, λ_{vv} , for buckling about the minor axis, v-v, as given by:

$$\lambda_{vv} = \frac{\left(\frac{l_{vv}}{r_{vv}} \right)}{\varepsilon \sqrt{\frac{\pi^2 E}{250}}}$$

l_{vv} = Laterally unsupported length preventing translation normal to the minor axis

r_{vv} = radius of gyration of the angle section about the minor axis

14.5.1.2 Loaded through one leg

The design strength of single angle members loaded in compression through one of its legs is affected by flexural torsional buckling and bending. The design compressive strength of such eccentrically loaded angle members, *in lieu of* a more exact second order design under combined bending axial compression, may be evaluated approximately as given below.

The design compressive strength, of single angles loaded through gusset connection to one leg parallel to the a-a axis (a-a axis being either the z-z or the y-y axis, depending on which leg is connected to the gusset) of the member may be calculated as:

$$f_{cde} = K_f \chi_{aa} f_y / \gamma_{m0}$$

where

χ_{aa} = Stress reduction factor (see Table 8) for buckling class 'b', calculated as per **14.1.12.1**, using the non-dimensional slenderness ratio, λ_{aa} .

$$K_f = k_1 + k_2 \lambda_{aa} + k_3 \lambda_{\phi},$$

where

K_f = modification factor to account for eccentric end connection

k_1, k_2, k_3 = constants depending upon the end condition, as given in Table 12,

$$\lambda_{aa} = \frac{\left(\frac{l_{aa}}{r_{aa}} \right)}{\varepsilon \sqrt{\frac{\pi^2 E}{250}}}$$

$$\lambda_{\phi} = \frac{(b_1 + b_2)/2t}{\varepsilon \sqrt{\frac{\pi^2 E}{250}}}$$

l_{aa} = center to center length of the lateral support preventing translation of the member perpendicular to a - a axis (a - a axis being either the z - z or the y - y axis, depending on which leg is connected to the gusset),

r_{aa} = radius of gyration of the angle member about the a - a axis (a - a axis being either the z - z or the y - y axis, depending on which leg is connected to the gusset), parallel to the plane of the end gusset plates,

b_1, b_2 = width of the connected and outstanding legs of the angle, respectively.

t = thickness of the leg, and

ε = is the yield stress ratio, $\sqrt{\frac{250}{f_y}}$, f_y being in MPa

Table 12 Constants k_1 , k_2 , and k_3
(Clause 14.5.1.2)

SI No.	End Connection	Gusset/Connecting Member Fixity ¹⁾	k_1	k_2	k_3
(1)	(2)	(3)	(4)	(5)	(6)
i)	Fully welded or connected with two or more bolts	Fixed	0.798	0.563	-2.072
		Hinged	0.401	0.420	-1.040
ii)	Single bolt	Fixed	0.418	0.547	-1.400
		Hinged	0.374	0.415	-2.072

¹⁾ In-plane rotational restraint provided to the gusset by the supporting member.
For partial restraint, k_i can be interpolated between the results for fixed and hinged cases.

14.5.2 Double Angle Struts

14.5.2.1 For double angle discontinuous struts, connected back to back, on opposite sides of the gusset or a section, by not less than two bolts or rivets in line along the angles at each end, or by the equivalent in welding, the load may be regarded as applied axially. The effective length, KL , in the plane of end gusset shall be taken as between 0.7 and 0.85 times the distance between intersections, depending on the degree of the restraint provided. The effective length, KL , in the plane perpendicular to that of the end gusset, shall be taken as equal to the distance between centers of intersections. The calculated average compressive stress shall not exceed the values based on **14.1.2**. The angles shall be connected together over their lengths so as to satisfy the requirements of **14.8** and **17.2.5**.

14.5.2.2 Double angle discontinuous struts connected back-to-back, to one side of a gusset or section by one or more bolts or rivets in each angle, or by the equivalent in welding, shall be designed in accordance with **14.5.1** and the angles shall be connected together over their lengths so as to satisfy the requirements of **14.8** and **17.2.5**.

14.5.3 Continuous Members

Double angle continuous struts such as those forming the flanges, chords or ties of trusses or trussed girders, or the legs of towers shall be designed as axially loaded compression members, and the effective length shall be taken in accordance with **14.2.4**.

14.5.4 Combined Stresses

In addition to axial loads, if the struts carry loads which cause transverse bending, the combined bending and axial stresses shall be checked in accordance with **15.3**. For determining the permissible axial and bending stresses, the effective length shall be taken in accordance with the **14.2** and **15.3**.

14.6 Laced Columns

14.6.1 General

14.6.1.1 Members comprising two main components laced and tied, should where practicable, have a radius of gyration about the axis perpendicular to the plane of lacing not less than the radius of gyration about the axis parallel to the plane of lacing [see Fig.10(a) and Fig. 10(b)].

14.6.1.2 As far as practicable, the lacing system shall be uniform throughout the length of the column.

14.6.1.3 Except for tie plates as specified in **14.7**, double laced systems [see Fig. 10(b)] and single laced systems [see Fig. 10(a)] on opposite sides of the main components shall not be combined with cross members (ties) perpendicular to the longitudinal axis of the

strut [see Fig. 10(c)], unless all forces resulting from deformation of the strut members are calculated and provided for in the design of lacing and its fastenings.

14.6.1.4 Single laced systems, on opposite faces of the components being laced together shall preferably be in the same direction so that one is the shadow of the other, instead of being mutually opposed in direction.

14.6.1.5 The effective slenderness ratio, $(KL/r)_e$, of laced columns shall be taken as 1.05 times the $(KL/r)_0$, the actual maximum slenderness ratio, in order to account for shear deformation effects.

14.6.2 *Width of Lacing Bars*

In bolted/riveted construction, the minimum width of lacing bars shall be three times the nominal diameter of the end bolt/rivet.

14.6.3 *Thickness of Lacing Bars*

The thickness of flat lacing bars shall not be less than one-fortieth of its effective length for single lacings and one-sixtieth of the effective length for double lacings.

14.6.3.1 Rolled sections or tubes of equivalent strength may be permitted instead of flats, for lacings.

14.6.4 *Angle of Inclination*

Lacing bars, whether in double or single systems, shall be inclined at an angle not less than 40° nor more than 70° to the axis of the built-up member.

14.6.5 *Spacing*

14.6.5.1 The maximum spacing of lacing bars, whether connected by bolting, riveting or welding, shall also be such that the maximum slenderness ratio of the components of the main member (a_1/r_1) , between consecutive lacing connections is not greater than 50 or 0.7 times the most unfavourable slenderness ratio of the member as a whole, whichever is less, where a_1 is the unsupported length of the individual member between lacing points, and r_1 is the minimum radius of gyration of the individual member being laced together.

14.6.5.2 Where lacing bars are not lapped to form the connection to the components of the members, they shall be so connected that there is no appreciable interruption in the triangulation of the system.

14.6.6 *Design of Lacings*

14.6.6.1 The lacing shall be proportioned to resist a total transverse shear, V_t , at any point in the member, equal to at least 2.5 percent of the axial force in the member and shall be divided equally among all transverse-lacing systems in parallel planes.

14.6.6.2 For members carrying calculated bending stress due to eccentricity of loading, applied end moments and/or lateral loading, the lacing shall be proportioned to resist the actual shear due to bending, in addition to that specified in **14.6.6.1**.

14.6.6.3 The slenderness ratio, KL/r , of the lacing bars shall not exceed 145. In bolted/riveted construction, the effective length of lacing bars for the determination of the design strength shall be taken as the length between the inner end fastener of the bars for single lacing, and as 0.7 of this length for double lacings effectively connected at intersections. In welded construction, the effective lengths shall be taken as 0.7 times the distance between the inner ends of welds connecting the single lacing bars to the members.

NOTE — The required section for lacing bars as compression/tension members shall be determined by using the appropriate design stresses, f_{cd} subject to the requirements in **14.6.3** to **14.6.6** and T_d in **12.1**.

14.6.7 *Attachment to Main Members*

The bolting, riveting or welding of lacing bars to the main members shall be sufficient to transmit the force calculated in the bars. Where welded lacing bars overlap the main members, the amount of lap measured along either edge of the lacing bar shall be not less than four times the thickness of the bar or the thickness of the element of the members to which it is connected, whichever is less. The welding should be sufficient to transmit the load in the bar and shall, in any case, be provided along each side of the bar for the full length of lap.

14.6.8 *End Tie Plates*

Laced compression members shall be provided with tie plates as per **14.7** at the ends of lacing systems and at intersection with other members/stays and at points where the lacing systems are interrupted.

FIG. 10(a) SINGLE LACED SYSTEM

FIG. 10(b) DOUBLE LACED SYSTEM

FIG. 10(c) DOUBLE LACED AND SINGLE LACED SYSTEM COMBINED WITH CROSS MEMBERS

FIG. 10 LACED COLUMNS

14.7 Battened Columns

14.7.1 General

14.7.1.1 Compression members composed of two main components battened should preferably have the individual members of the same cross section and symmetrically disposed about their major axis. Where practicable, the compression members should have a radius of gyration about the axis perpendicular to the plane of the batten not less than the radius of gyration about the axis parallel to the plane of the batten (see Fig. 11).

14.7.1.2 Battened compression members, not complying with the requirements specified in this Section or those subjected to eccentricity of loading, applied moments or lateral forces in the plane of the battens (see Fig. 11), shall be designed according to the exact theory of elastic stability or empirically, based on verification by tests.

NOTE — If the column section is subjected to eccentricity or other moments about an axis perpendicular to battens, the battens and the column section should be specially designed for such moments and shears.

14.7.1.3 The battens shall be placed opposite to each other at each end of the member and at points where the member is stayed in its length and as far as practicable, be spaced and proportioned uniformly throughout. The number of battens shall be such that the member is divided into not less than three bays within its actual length from centre to centre of end connections.

14.7.1.4 The effective slenderness ratio $(KL/r)_e$ of battened columns, shall be taken as 1.1 times the $(KL/r)_0$, the maximum actual slenderness ratio of the column, to account for shear deformation effects.

14.7.2 Design of Battens

14.7.2.1 Battens

Battens shall be designed to carry the bending moments and shear forces arising from transverse shear force V_t equal to 2.5 percent of the total axial force on the whole compression member, at any point in the length of the member, divided equally between parallel planes of battens. Battened member carrying calculated bending moment due to eccentricity of axial loading, calculated end moments

FIG. 11 BATTEN COLUMN SECTION

or lateral loads parallel to the plane of battens, shall be designed to carry actual shear in addition to the above shear. The main members shall also be checked for the same shear force and bending moments as for the battens.

Battens shall be of plates, angles, channels, or I-sections and at their ends shall be riveted, bolted or welded to the main components so as to resist simultaneously a shear $V_b = V_t C/NS$ along the column axis and a moment $M = V_t C/2N$ at each connection,

where

V_t = transverse shear force as defined above;

C = distance between centre-to-centre of battens, longitudinally;

N = number of parallel planes of battens; and

S = minimum transverse distance between the centroid of the rivet/bolt group/welding connecting the batten to the main member.

14.7.2.2 Tie plates

Tie plates are members provided at the ends of battened and laced members, and shall be designed by the same method as battens. In no case shall a tie plate and its fastenings be incapable of carrying the forces for which the lacing or batten has been designed.

14.7.2.3 Size

When plates are used for battens, the end battens and those at points where the member is stayed in its length shall have an effective depth, longitudinally, not less than the perpendicular distance between the centroids of the main members. The intermediate battens shall have an effective depth of not less than three quarters of this distance, but in no case shall the effective depth of any batten be less than twice the width of one member, in the plane of the battens. The effective depth of a batten shall be taken as the longitudinal distance between outermost bolts, rivets or welds at the ends. The thickness of batten or the tie plates shall be not less than one fiftieth of the distance between the innermost connecting lines of rivets, bolts or welds, perpendicular to the main member.

14.7.2.4 The requirement of bolt size and thickness of batten specified above does not apply when angles, channels or I-sections are used for battens with their legs or flanges perpendicular to the main member. However, it should be ensured that the ends of the compression members are tied to achieve adequate rigidity.

14.7.3 Spacing of Battens

14.7.3.1 In battened compression members where the individual members are not specifically checked for shear stress and bending moments, the spacing of battens, centre-to-centre of its end fastenings, shall be such that the slenderness ratio (KL/r) of any component over that distance shall be not greater than 50 nor greater than 0.7 times the slenderness ratio of the member as a whole about its z-z axis (parallel to the battens).

14.7.4 Attachment to Main Members

14.7.4.1 Welded connections

Where tie or batten plates overlap the main members, the amount of lap shall be not less than four times the thickness of the plate. The length of weld connecting each edge of the batten plate to the member shall, in aggregate, be not less than half the depth of the batten plate. At least one-third of the weld shall be placed at each end of this edge. The length of weld and depth of batten plate shall be measured along the longitudinal axis of the main member.

In addition, the welding shall be returned along the other two edges of the plates transversely to the axis of the main member for a length not less than the minimum lap specified above.

14.8 Compression Members Composed of Two Components Back-to-Back

14.8.1 Compression members composed of two angles, channels, or tees back-to-back in contact or separated by a small distance, shall be connected together by riveting, bolting or welding so that the ratio of most unfavorable slenderness of each member between the intermediate connections is not greater than 40 or 0.6 times the most unfavorable ratio of slenderness of the strut as a whole, whichever is less [see **17**].

14.8.2 In no case shall the ends of the strut be connected together with less than two rivets or bolts or their equivalent in welding, and there shall be not less than two additional connections in between, spaced equidistant along the length of the strut. Where the members are separated back-to-back, the rivets or bolts through these connections shall pass through solid washers or packing in between. Where the legs of the connected angles or the connected tees are 125 mm wide or more, or where webs of channels are 150 mm wide or over, not less than two rivets or bolts shall be used in each connection, one on line of each gauge mark.

14.8.3 Where these connections are made by welding, solid packing shall be used to effect the jointing unless the members are sufficiently close together to permit direct welding, and the members shall be connected by welding along both pairs of edges of the main components.

14.8.4 The rivets, bolts or welds in these connections shall be sufficient to carry the shear force and moments, if any, specified for battened struts (see **14.7.3**), and in no case shall the rivets or bolts be less than 16 mm diameter for members up to and including 10 mm thick; 20 mm diameter for members up to and including 16 mm thick; and 22 mm diameter for members over 16 mm thick.

14.8.4.1 Compression members connected by such riveting, bolting or welding shall not be subjected to transverse loading in a plane perpendicular to the riveted, bolted or welded surfaces.

14.8.5 Where the components are in contact back-to-back, the spacing of the rivets, bolts or intermittent welds shall not exceed the maximum spacing for compression members as given under **17**.

15 DESIGN OF MEMBERS SUBJECTED TO BENDING

15.1 General

Members subjected to predominant bending shall have adequate design strength to resist bending moment, shear force, and concentrated forces imposed upon and their combinations. Further, the members shall satisfy the deflection limitation presented under **12**, as serviceability criteria. Member subjected to other forces in addition to bending or biaxial bending shall be designed in accordance with the provisions under **16**.

15.1.1 Effective Span of Beams

The effective span of a beam shall be taken as the distance between the centres of the supports, except where the point of application of the reaction is taken as eccentric at the support, when it shall be permissible to take the effective span as the length between the assumed lines of the reactions.

15.2 Design Strength in Bending (Flexure)

The design bending strength of beam, adequately supported against lateral torsional buckling (laterally supported beam) is governed by the yield stress (see **15.2.1**). When a beam is not adequately supported against lateral buckling (laterally un-supported beams) the design bending strength may be governed by lateral torsional buckling strength (see **15.2.2**).

The factored design moment, M at any section, in a beam due to external actions, shall satisfy

$$M \leq M_d$$

where

M_d = design bending strength of the section, calculated as given in **15.2.1.2**.

15.2.1 Laterally Supported Beam

A beam may be assumed to be adequately supported at the supports, provided the compression flange has full lateral restraint and nominal torsional restraint at supports supplied by web cleats, partial depth end plates, fin plates or continuity with the adjacent span. Full lateral restraint to compression flange may be assumed to exist if the frictional or other positive restraint of a floor connection to the compression flange of the member

is capable of resisting a lateral force not less than 2.5 percent of the maximum force in the compression flange of the member. This may be considered to be uniformly distributed along the flange, provided gravity loads constitute the dominant loading on the member and the floor construction is capable of resisting this lateral force.

The design bending strength of a section which are not susceptible to web buckling under shear before yielding (where $d/t_w \leq 67 \varepsilon$) shall be determined according to **15.2.1.2**.

15.2.1.1 *Section with webs susceptible to shear buckling before yielding*

When the flanges are plastic, compact or semi-compact but the web is susceptible to shear buckling before yielding (see **15.4.2.1**), the design bending strength shall be calculated using one of the following methods:

- a) The bending moment and axial force acting on the section may be assumed to be resisted by flanges only and the web is designed only to resist shear (see **15.4**).
- b) The bending moment and axial force acting on the section may be assumed to be resisted by the whole section. In such a case, the web shall be designed for combined shear and normal stresses using simple elastic theory in case of semi-compact webs and simple plastic theory in the case of compact and plastic webs.

15.2.1.2 When the factored design shear force does not exceed $0.6 V_d$, where V_d is the design shear strength of the cross section (see **15.4**), the design bending strength, M_d shall be taken as:

$$M_d = \beta_b Z_p f_y / \gamma_{m0}$$

To avoid irreversible deformation under serviceability loads, M_d shall be less than $1.2 Z_e f_y / \gamma_{m0}$ in case of simply supported and $1.5 Z_e f_y / \gamma_{m0}$ in case of cantilever beams;

where

$\beta_b = 1.0$ for plastic and compact sections;

$\beta_b = Z_e / Z_p$ for semi-compact sections;

Z_p, Z_e = plastic and elastic section moduli of the cross section, respectively;

f_y = yield stress of the material; and

γ_{m0} = partial safety factor (see **12.4.1**).

15.2.1.3 When the design shear force (factored), V exceeds $0.6 V_d$, where V_d is the design shear strength of the cross section (see **15.4**) the design bending strength, M_d shall be taken as:

$$M_d = M_{dv}$$

where

M_{dv} = design bending strength under high shear as defined in **16.2**.

15.2.1.4 Holes in the tension zone

- a) The effect of holes in the tension flange, on the design bending strength need not be considered if

$$(A_{nf}/A_{gf}) \geq (f_y/f_u) (\gamma_{m1}/\gamma_{m0}) / 0.9$$

where

A_{nf}/A_{gf} = ratio of net to gross area of the flange in tension;
 f_y/f_u = ratio of yield and ultimate stress of the material; and
 γ_{m1}/γ_{m0} = ratio of partial safety factors against ultimate to yield stress (see **12.4.1**).

When the A_{nf}/A_{gf} does not satisfy the above requirement, the reduced effective flange area, A_{ef} satisfying the above equation may be taken as the effective flange area in tension, instead of A_{gf} .

- b) The effect of holes in the tension region of the web on the design flexural strength need not be considered, if the limit given in **15.2.1.4(a)** above is satisfied for the complete tension zone of the cross section, comprising the tension flange and tension region of the web.
- c) Fastener holes in the compression zone of the cross section need not be considered in design bending strength calculation, except for oversize and slotted holes or holes without any fastener.

15.2.1.5 Shear lag effects

The shear lag effects in flanges may be disregarded provided:

- a) For outstand elements (supported along one edge), $b_o \leq L_o / 20$; and
 b) For internal elements (supported along two edges), $b_i \leq L_o / 10$.

where

L_o = length between points of zero moment (inflection) in the span,
 b_o = width of the flange with outstand, and
 b_i = width of the flange as an internal element

Where these limits are exceeded, the effective width of flange for design strength may be calculated using specialist literature, or conservatively taken as the value satisfying the limit given above.

15.2.2 Laterally Unsupported Beams

Resistance to lateral torsional buckling need not be checked separately (member may be treated as laterally supported, see **15.2.1**) in the following cases:

- a) Bending is about the minor axis of the section,
- b) Section is hollow (rectangular/ tubular) or solid bars, and
- c) In case of major axis bending, λ_{LT} (as defined herein) is less than 0.4.

The design bending strength of laterally unsupported beam as governed by lateral torsional buckling is given by:

$$M_d = \beta_b Z_p f_{bd}$$

where

$$f_{bd} = \chi_{LT} f_y / \gamma_{m0}$$

$$\beta_b = 1.0 \text{ for plastic and compact sections;}$$

$$= Z_e/Z_p \text{ for semi-compact sections (Class 3);}$$

$$= Z_{eff}/Z_p \text{ for Non-compact sections (Class 4)}$$

Z_p, Z_e, Z_{eff} = plastic section modulus and elastic section modulus (Class 3) and effective section modulus (class 4) with respect to extreme compression fibre;

χ_{LT} = bending stress reduction factor to account for lateral torsional buckling, in doubly symmetrical sections with lateral support at the ends given by:

$$\chi_{LT} = \frac{f_m}{\{\varphi_{LT} + [\varphi_{LT}^2 - f_m \lambda_{LT}^2]^{0.5}\}} \leq 1.0$$

$$\varphi_{LT} = 0.5 \left[1 + f_m \left(\left(\frac{\lambda_{LT}}{\lambda_y} \right)^2 \alpha_{LT} (\lambda_{LT} - 0.2) + \lambda_{LT}^2 \right) \right]$$

α_{LT} = the imperfection parameter is given in Table 13

f_m = the moment gradient effect parameter given in the table 14

The non-dimensional slenderness ratio, λ_{LT} , is given by

$$\lambda_{LT} = \sqrt{\beta_b Z_p f_y / M_{crLT}} \leq \sqrt{1.2 Z_e f_y / M_{crLT}}$$

$$= \sqrt{f_y / f_{crLT}}$$

$$\lambda_y = \sqrt{f_y / f_{cry}}$$

where

M_{crLT} = elastic lateral torsional buckling moment calculated in accordance with **15.2.2.1**, and

f_{crLT} = extreme fibre bending compressive stress corresponding to elastic lateral torsional buckling moment (see **15.2.2.1**).

f_{cry} = the non-dimensional weak axis slenderness ratio for laterally supported length equal to distance between lateral supports to the compression flange.

Table 13 Imperfection Parameter, α_{LT} for Lateral Torsional Buckling of Beams
(Clause 15.2.2)

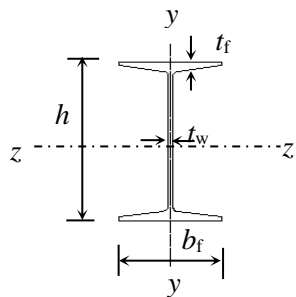

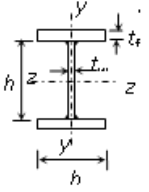

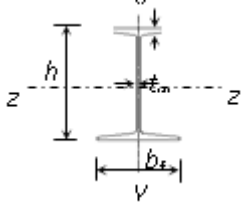

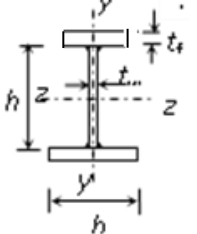

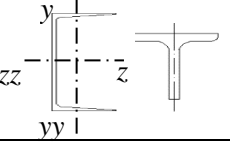

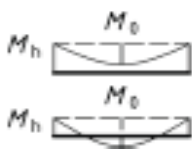

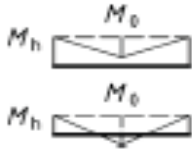

Cross section	Limits		α_{LT}
Rolled I or H Sections 	$h/b > 1.2$	$t_f \leq 40 \text{ mm}$	$0.12 \sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.34$
		$t_f > 40 \text{ mm}$	$0.16 \sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.49$
	$h/b > 1.2$	----	$0.12 \sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.34$
Welded I Sections 	$t_f \leq 40 \text{ mm}$		$0.12 \sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.34$
	$t_f > 40 \text{ mm}$		$0.12 \sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.34$
Rolled unequal I or H Sections 	$h/b_{min} \leq 2.0$		0.21
	$h/b_{min} > 2.0$		0.34
Welded unequal I section 	$h/b_{min} \leq 2.0$		0.49
	$h/b_{min} > 2.0$		0.76
Other rolled sections 	-----		0.76
NOTE: The selection of lateral torsional buckling imperfection factor is based on b_{min} irrespective of it being tension or compression flange.			

Table 14 Moment Gradient Effect Parameter
(Clause 15.2.2)

Load case	Factor f_M
$M = \text{uniform}$ 	1,0
 $-1 \leq \psi \leq +1$	$1,25 - 0,1\psi - 0,15\psi^2$
	1,05

	For $0 \leq \frac{M_0}{M_h} < 1,47$: $1,25 + 0,5 \left(\frac{M_0}{M_h} \right)^2 - 0,275 \left(\frac{M_0}{M_h} \right)^4$ For $\frac{M_0}{M_h} \geq 1,47$: 1,05
	1,10
	For $0 \leq \frac{M_0}{M_h} < 2,0$: $1,0 + 1,25 \frac{M_0}{M_h} - 0,30 \left(\frac{M_0}{M_h} \right)^3$ For $\frac{M_0}{M_h} \geq 2,0$: 1,10
	For $0 \leq \frac{M_0}{M_h} < 1,5$: $1,25 + 0,325 \left(\frac{M_0}{M_h} \right)^2 - 0,175 \left(\frac{M_0}{M_h} \right)^4$ For $\frac{M_0}{M_h} \geq 1,50$: 1,10

15.2.2.1 Elastic lateral torsional buckling moment

In case of simply supported, prismatic members with symmetric cross section, the elastic lateral buckling moment, M_{cr} , can be determined from:

$$M_{cr} = \sqrt{\left\{ \left(\frac{\pi^2 E I_y}{(L_{LT})^2} \right) \left[G I_t + \frac{\pi^2 E I_w}{(L_{LT})^2} \right] \right\}} = \beta_b Z_p f_{cr,b}$$

$f_{cr,b}$ of non-slender rolled steel sections in the above equation may be approximately calculated from the following equation:

$$f_{cr,b} = \frac{1.1 \pi^2 E}{(L_{LT} / r_y)^2} \left[1 + \frac{1}{20} \left(\frac{L_{LT} / r_y}{h_f / t_f} \right)^2 \right]^{0.5}$$

where

- I_t = torsional constant = $\sum b_i t_i^3 / 3$ for open section;
- I_w = warping constant;
- I_y, r_y = moment of inertia and radius of gyration, respectively about the weaker axis;
- L_{LT} = effective length for lateral torsional buckling (see **15.3**);
- h_f = center to center distance between flanges; and
- t_f = thickness of the flange.

M_{cr} for different beam sections, considering loading, support condition, and asymmetric section, shall be more accurately calculated using the method given in Annex E. The above equations for calculating M_{cr} may be conservatively used for channel sections.

15.3 Effective Length for Lateral Torsional Buckling

15.3.1 For simply supported beams and girders of span length, L , where no lateral restraint to the compression flanges is provided, but where each end of the beam is restrained against torsion, the effective length L_{LT} of the lateral buckling to be used in **15.2.2.1** shall be taken as in Table 15.

In simply supported beams with intermediate lateral restraints against lateral torsional buckling, the effective length for lateral torsional buckling, L_{LT} to be used in **15.2.2.1**, shall be taken as the length of the relevant segment in between the lateral restraints. In the case of intermediate partial lateral restraints, the effective length, L_{LT} shall be taken as equal to 1.2 times the length of the relevant segment in between the partial lateral restraints.

Restraint against torsional rotation at supports in these beams may be provided by,

- a) web or flange cleats, or
- b) bearing stiffeners acting in conjunction with the bearing of the beam, or
- c) lateral end frames or external supports providing lateral restraint to the compression flanges at the ends, or
- d) their being built into walls.

Table 15 Effective Length for Simply Supported Beams, L_{LT}
(Clause 15.3.1)

SI No.	Conditions of Restraint at Supports		Loading Condition	
	Torsional restraint	Warping Restraint	Normal	Destabilizing
(1)	(2)	(3)	(4)	(5)
i)	Fully restrained	Both flanges fully restrained	$0.70 L$	$0.85 L$
ii)	Fully restrained	Only compression flange fully restrained	$0.75 L$	$0.90 L$
iii)	Fully restrained	Both flanges partially restrained	$0.80 L$	$0.95 L$
iv)	Fully restrained	Only compression flange partially restrained	$0.85 L$	$1.00 L$
v)	Fully restrained	No restraint in both flanges	$1.00 L$	$1.20 L$
vi)	Partially restrained by bottom flange support connection	No restraint in both flanges	$1.0 L + 2D$	$1.2 L + 2D$
vii)	Partially restrained by bottom flange bearing support	No restraint in both flanges	$1.2 L + 2D$	$1.4 L + 2D$

NOTES

- 1 Torsional restraint prevents rotation about the longitudinal axis.
- 2 Warping restraint prevents rotation of the flange in its plane.
- 3 D is the overall depth of the beam.
- 4 In case of continuous beams, L shall be taken as the distance between points of inflection, and the restraint conditions at the point of inflections should be considered.

15.3.2 For beams, which are provided with members giving effective lateral restraint to the compression flange at intervals along the span, in addition to the end torsional

restraint required in **15.3.1**, the effective length for lateral torsional buckling shall be taken as the distance, centre-to-centre of the restraint members in the relevant segment under normal loading condition and 1.2 times this distance, where the load is not acting on the beam at or above the shear centre and towards the shear centre, so as to have destabilizing effect during lateral torsional buckling deformation.

15.3.3 For cantilever beams of projecting length L , the effective length L_{LT} to be used in **15.2.2.1** shall be taken as in Table 16 for different support conditions.

15.3.4 Where a member is provided intermediate lateral supports to improve the lateral buckling strength, these restraints should have sufficient strength and stiffness to prevent lateral movement of the compression flange at that point, relative to the end supports. The intermediate lateral restraints should be either connected to an appropriate bracing system capable of transferring the restraint force to the effective lateral support at the ends of the member, or should be connected to an independent robust part of the structure capable of transferring the restraint force. Two or more parallel member requiring such lateral restraint shall not be simply connected together assuming mutual dependence for the lateral restraint.

The intermediate lateral restraints should be connected to the member as close to the compression flange as practicable. Such restraints should be closer to the shear centre of the compression flange than to the shear centre of the section. However, if torsional restraint preventing relative rotation between the two flanges is provided, the intermediate lateral restraint may be connected at any appropriate level.

For beams which are provided with members giving effective lateral restraint at intervals along the span, the effective lateral restraint shall be capable of resisting a force of 2.5 percent of the maximum force in the compression flange taken as divided equally between the points at which the restraint members are provided. Further, each restraint point should be capable of resisting 1 percent of the maximum force in the compression flange.

15.3.4.1 In a series of such beams, with solid webs, which are connected together by the same system of restraint members, the sum of the restraining forces required shall be taken as 2.5 percent of the maximum flange force in one beam only.

15.3.4.2 In the case of a series of latticed beams, girders or roof trusses which are connected together by the same system of restraint members, the sum of the restraining forces required shall be taken as 2.5 percent of the maximum force in the compression flange plus 1.25 percent of this force for every member of the series other than the first, up to a maximum total of 7.5 percent.

15.3.5 Purlins adequately restrained by sheeting need not be normally checked for the restraining forces required by rafters, roof trusses or portal frames that carry predominately roof loads provided there is bracing of adequate stiffness in the plane of rafters or roof sheeting which is capable of acting as a stressed skin diaphragm.

15.3.6 In case of beams with double curvature bending, adequate direct lateral support to the compression flange in the hogging moment region may be provided as given above for simply supported beam. The effect of support to the tension (top) flange in the hogging moment region on lateral restraint to the compression flange may be considered as per specialist literature.

15.4 Shear

The factored design shear force, V , in a beam due to external actions shall satisfy

$$V \leq V_d$$

where

$$\begin{aligned} V_d &= \text{design strength} \\ &= V_n / \gamma_{m0} \end{aligned}$$

where

γ_{m0} = partial safety factor against shear failure (see **12.4.1**).

The nominal shear strength of a cross section, V_n , may be governed by plastic shear resistance (see **15.4.1**) or strength of the web as governed by shear buckling (see **15.4.2**).

15.4.1 The nominal plastic shear resistance under pure shear is given by:

$$V_n = V_p$$

where

$$V_p = \frac{A_v f_{yw}}{\sqrt{3}}$$

A_v = shear area; and

f_{yw} = yield strength of the web.

15.4.1.1 The shear area may be calculated as given below:

a) I-and channel sections:

Major Axis Bending:

Hot-rolled : $h t_w$

Welded : $d t_w$

Minor Axis Bending:

Hot-rolled or welded : $2 b t_f$

b) Rectangular hollow sections of uniform thickness:

Loaded parallel to depth (h) : $A h / (b+h)$

Loaded parallel to width (b) : $A b / (b+h)$

c) Circular hollow tubes of uniform thickness : $2A / \pi$

d) Plates and solid bars : A

where

A = cross section area,
 b = overall breadth of tubular section, breadth of I-section flanges,
 d = clear depth of the web between flanges,
 h = overall depth of the section,
 t_f = thickness of the flange, and
 t_w = thickness of the web.

NOTE – Fastener holes need not be accounted for in plastic design shear strength calculation provided that:

$$A_{vn} \geq (f_y / f_u) (\gamma_{m1} / \gamma_{m0}) A_w / 0.9$$

If A_{vn} does not satisfy the above condition, the effective shear area may be taken as that satisfying the above limit. Block shear failure criteria may be verified at the end connections. Provisions given under **16** may be referred to for design strength under combined high shear and bending.

15.4.2 Resistance to Shear Buckling

15.4.2.1 Resistance to shear buckling shall be verified as specified, when

$$\begin{aligned} d/t_w &> 67\varepsilon_w \quad \text{for a web without stiffeners, and} \\ &> 67\varepsilon_w \sqrt{\frac{K_v}{5.35}} \quad \text{for a web with stiffeners} \end{aligned}$$

where

$$\begin{aligned} K_v &= \text{shear buckling coefficient (see 15.4.2.2), and} \\ \varepsilon_w &= \sqrt{250/f_{yw}} \end{aligned}$$

15.4.2.2 Shear buckling design methods

The nominal shear strength, V_n , of webs with or without intermediate stiffeners as governed by buckling may be evaluated using one of the following methods:

a) *Simple post-critical method* – The simple post critical method, based on the shear buckling strength can be used for webs of I-section girders, with or without intermediate transverse stiffener, provided that the web has transverse stiffeners at the supports. The nominal shear strength is given by:

$$V_n = V_{cr}$$

where

V_{cr} = shear force corresponding to web buckling

$$= A_v \tau_b$$

where

τ_b = shear stress corresponding to web buckling, determined as follows:

- 1) when $\lambda_w \leq 0.8$, $\tau_b = f_{yw} / \sqrt{3}$
- 2) when $0.8 < \lambda_w < 1.2$, $\tau_b = [1 - 0.8(\lambda_w - 0.8)](f_{yw} / \sqrt{3})$
- 3) when $\lambda_w \geq 1.2$, $\tau_b = f_{yw} / (\sqrt{3} \lambda_w^2)$

where

λ_w = Non-dimensional web slenderness ratio for shear buckling stress, given by:

$$\lambda_w = \sqrt{f_{yw} / (\sqrt{3} \tau_{cr,e})}$$

$$\tau_{cr,e} = \text{the elastic critical shear stress of the web} = \frac{K_v \pi^2 E}{12(1 - \mu^2) [d/t_w]^2}$$

where

μ = Poisson's ratio, and

$K_v = 5.35$ when transverse stiffeners are provided only at supports

$$= 4.0 + 5.35 / (c/d)^2 \text{ for } c/d < 1.0$$

$$= 5.35 + 4.0 / (c/d)^2 \text{ for } c/d \geq 1.0$$

where c , d are the spacing of transverse stiffeners and depth of the web, respectively.

b) *Tension field method* – The tension field method, based on the post-shear buckling strength, may be used for webs with intermediate transverse stiffeners, in addition to the transverse stiffeners at supports, provided the panels adjacent to the panel under tension field action, or the end posts provide anchorage for the tension fields and if $c/d \geq 1.0$, where c , d are the spacing of transverse stiffeners and depth of the web, respectively.

In the tension field method, the nominal shear resistance, V_n , is given by:

$$V_n = V_{tf}$$

where

$$V_{tf} = [A_v \tau_b + 0.9 w_{tf} t_w f_v \sin \phi] \leq V_p$$

where

τ_b = shear stress corresponding to buckling of web **15.4.2.2(a)**;

f_v = yield strength of the tension field obtained from $\left[f_{yw}^2 - 3 \tau_b^2 + \psi^2 \right]^{0.5} - \psi$;

$$\psi = 1.5 \tau_b \sin 2\phi;$$

$$\phi = \text{inclination of the tension field nearly} = \tan^{-1} \frac{\left(\frac{d}{c}\right)}{1.5};$$

w_{tf} = width of the tension field, given by:

$$= d \cos \phi - (c - s_c - s_t) \sin \phi;$$

f_{yw} = yield stress of the web;

d = depth of the web;

c = spacing of transverse stiffeners in the web; and

s_c, s_t = anchorage lengths of tension field along the compression and tension flange respectively, obtained from:

$$s = \frac{2}{\sin \phi} \left[\frac{M_{fr}}{f_{yw} t_w} \right]^{0.5} \leq c$$

where

M_{fr} = reduced plastic moment capacity of the respective flange plate (disregarding any edge stiffener) after accounting for the axial force, N_f in the flange, due to overall bending and any external axial force in the cross section, and is calculated as :

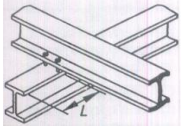

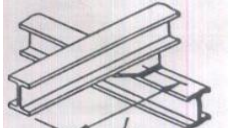

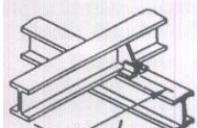

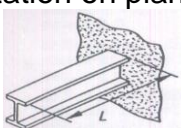

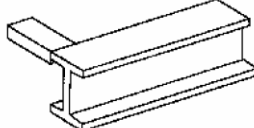

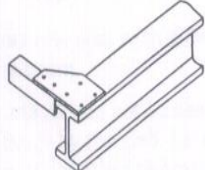

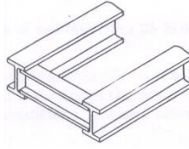

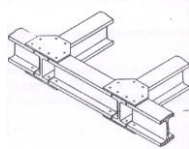

$$M_{fr} = 0.25 b_f t_f^2 f_{yf} \left[1 - \left\{ N_f / (b_f t_f f_{yf} / \gamma_{m0}) \right\}^2 \right]$$

where

b_f, t_f = width and thickness of the relevant flange respectively; and

f_{yf} = Yield stress of the flange.

15.5 Stiffened Web Panels

15.5.1 End Panels Design (see Fig.12)

The girders in which the interior panel (panel A) is designed using tension field action, the end panels shall be designed using only simple post critical method, according to **15.4.2.2(a)**.

Additionally, the end panel along with the stiffeners should be checked as a beam spanning between the flanges to resist a shear force, R_{tf} , and a moment, M_{tf} , due to tension field forces as given in **15.5.3**. Further, end stiffener should be capable of resisting the reaction plus a compressive force due to the moment, equal to M_{tf} [see Fig. (12)].

15.5.2 End Panels Designed Using Tension Field Action (see Fig. 13 and Fig. 14)

The end panel (Panel A) shall be designed according to **15.4.2.2(b)**.

Additionally, it should be provided with an end post consisting of a single or double stiffener, (see Fig. 13 and Fig. 14), satisfying the following.

- a) *Single stiffener* (see Fig. 13) – The top of the end post should be rigidly connected to the flange using full strength welds.

The end post should be capable of resisting the reaction plus a moment from the anchor forces equal to $2/3 M_{tf}$ due to tension field forces, where M_{tf} is obtained from **15.5.3**. The width and thickness of the end post are not to exceed the width and thickness of the flange.

- b) *Double stiffener* (see Fig. 14) – The end post should be checked as a beam spanning between the flanges of the girder and capable of resisting a shear force R_{tf} and a moment, M_{tf} due to the tension field forces as given in **15.5.3**.

15.5.3 Anchor Forces

The resultant longitudinal shear, R_{tf} , and a moment M_{tf} from the anchor of tension field forces are evaluated as given below:

$$R_{tf} = \frac{H_q}{2} \quad \text{and} \quad M_{tf} = \frac{H_q d}{10}$$

where

$$H_q = 1.25V_p \left(1 - \frac{V_{cr}}{V_p} \right)^{1/2}$$

$$V_p = \frac{d t f_y}{\sqrt{3}}$$

d = web depth,

If the actual factored shear force, V in the panel designed using tension field approach is less than the shear strength, V_{tf} as given in **15.4.2.2(b)**, then the values of H_q may be reduced by the ratio $\frac{V - V_{cr}}{V_{tf} - V_{cr}}$

where

V_{tf} = basic shear strength for the panel utilizing tension field action as given in **15.4.2.2(b)**, and

V_{cr} = critical shear strength for the panel designed utilizing tension field action as given in **15.4.2.2(a)**.

NOTES

- 1 Panel A is designed utilizing tension field action as given in **15.4.2.2(b)**.
- 2 Panel B is designed using simple post critical method as given in **15.4.2.2(a)**.
- 3 Bearing stiffener is designed for the compressive force due to bearing plus compressive force due to the moment M_{tf} as given in **15.5.3**.

FIG. 12 END PANEL DESIGNED NOT USING TENSION FIELD ACTION

NOTES

- 1 Panel A is designed utilizing tension field action as given in **15.4.2.2(b)**.
- 2 Bearing stiffener and end post is designed for combination of compressive loads due to bearing and a moment equal to $2/3 M_{tf}$ as given in **15.5.3**.

FIG. 13 END PANEL DESIGNED USING TENSION FIELD ACTION
(SINGLE STIFFENER)

NOTE

- 1 Panel A is designed utilizing tension field action as given in **15.4.2.2(b)**
- 2 Bearing stiffener is designed for compressive force due to bearing as given in **15.4.2.2(a)**
- 3 End post is designed for horizontal shear R_{tf} and moment M_{tf} as given in **15.5.3**

FIG. 14 END PANEL DESIGNED USING TENSION FIELD ACTION
(DOUBLE STIFFENER)

15.5.4 Panels with Openings – Panels with opening of dimension greater than 10 percent of the minimum panel dimension should be designed without using tension field action as given in **15.4.2.2(b)**. The adjacent panels should be designed as an end panel as given in **15.5.1** or **15.5.2**, as appropriate.

15.6 Design of Beams and Plate Girders with Solid Webs

15.6.1 Minimum Web Thickness

The thickness of the web in a section shall satisfy the following requirements:

15.6.1.1 Serviceability requirement

a) when transverse stiffeners are not provided,

$$1) \frac{d}{t_w} \leq 200 \varepsilon_w \text{ (web connected to flanges along both longitudinal edges)}$$

2) $\frac{d}{t_w} \leq 90\epsilon_w$ (web connected to flanges along one longitudinal edge only),

b) when only transverse stiffeners are provided (in webs connected to flanges along both longitudinal edges),

1) when $3d \geq c \geq d$

$$\frac{d}{t_w} \leq 200\epsilon_w$$

2) when $0.74 d \leq c < d$

$$\frac{c}{t_w} \leq 200\epsilon_w$$

3) when $c < 0.74d$

$$\frac{d}{t_w} \leq 270\epsilon_w$$

4) when $c > 3d$, the web shall be considered as unstiffened,

c) when transverse stiffeners and longitudinal stiffeners at one level only are provided ($0.2 d$ from compression flange) according to **15.7.13(a)**,

1) when $2.4d \geq c \geq d$

$$\frac{d}{t_w} \leq 250\epsilon_w$$

2) when $0.74 d \leq c \leq d$

$$\frac{c}{t_w} \leq 250\epsilon_w$$

3) when $c < 0.74 d$

$$\frac{d}{t_w} \leq 340\epsilon_w$$

d) when a second longitudinal stiffener (located at neutral axis is provided)

$$\frac{d}{t_w} \leq 400\epsilon_w$$

where

d = depth of the web,

t_w = thickness of the web,

c = spacing of transverse stiffener (see Fig. 12 and Fig. 13),

ϵ_w = yield stress ratio of web = $\sqrt{250/f_{yw}}$, and

f_{yw} = yield stress of the web.

15.6.1.2 Compression flange buckling requirement

In order to avoid buckling of the compression flange into the web, the web thickness shall satisfy the following:

a) When transverse stiffeners are not provided,

$$\frac{d}{t_w} \leq 345 \varepsilon_f^2$$

b) When transverse stiffeners are provided, and

i) when $c \geq 1.5 d$

$$\frac{d}{t_w} \leq 345 \varepsilon_f^2$$

ii) when $c < 1.5 d$

$$\frac{d}{t_w} \leq 345 \varepsilon_f$$

where

d = depth of the web,

t_w = thickness of the web,

c = spacing of transverse stiffener (see Fig. 12 and Fig. 13),

ε_f = yield stress ratio of flange = $\sqrt{250/f_{yf}}$, and

f_{yf} = yield stress of compression flange.

15.6.2 Sectional Properties

15.6.2.1 The effective sectional area of compression flanges shall be the gross area with deductions for excessive width of plates as specified for compression members [see **14**] and for open holes occurring in a plane perpendicular to the direction of stress at the section being considered (see **15.2.1.4**).

The effective sectional area of tension flanges shall be the gross sectional area with deductions for holes as specified in **15.2.1.4**.

The effective sectional area for parts in shear shall be taken as specified in **15.4.1.1**.

15.6.3 Flanges

15.6.3.1 In riveted or bolted construction, flange angles shall form as large a part of the area of the flange as practicable (preferably not less than one-third) and the number of flange plates shall be kept to a minimum.

In exposed situations, where flange angles are used, at least one plate of the top flange shall extend over the full length of the girder, unless the top edge of the web is machined flush with the flange angles. Where two or more flange plates are used, tacking rivets shall be provided, if necessary to comply with the requirements of Section 6(k).

Each flange plate shall extend beyond its theoretical cut-off point, and the extension shall contain sufficient rivets, bolts or welds to develop in the plate, the load calculated for the bending moment on the girder section (taken to include the curtailed plate) at the theoretical cut-off point.

The outstand of flange plates, that is the projection beyond the outer line of connections to flange angles, channel or joist flanges or in the case of welded constructions their projection beyond the face of the web or tongue plate, shall not exceed the values given in **10.7.2** (see Table 2).

In the case of box girders, the thickness of any plate, or the aggregate thickness of two or more plates, when these plates are tacked together to form the flange, shall satisfy the requirements given in **10.7.2** (see Table 2).

15.6.3.2 *Flange splices*

Flange splices should preferably, not be located at points of maximum stress. Where splice plates are used, their area shall be not less than 5 percent in excess of the area of the flange element spliced; their centre of gravity shall coincide, as nearly as possible, with that of the element spliced. There shall be enough bolts, rivets or welds on each side of the splice to develop the load in the element spliced plus 5 percent but in no case should the strength developed be less than 50 percent of the effective strength of the material spliced. In welded construction, flange plates shall be joined by complete penetration butt welds, wherever possible. These butt welds shall develop the full strength of the plates.

15.6.3.3 *Connection of flanges to web*

The flanges of plate girders shall be connected to the web by sufficient rivets, bolts or welds to transmit the maximum horizontal shear force resulting from the bending moment gradient in the girder, combined with any vertical loads which are directly applied to the flange. If the web is designed using tension field method as given in **15.4.2.2** (b), the weld should be able to transfer the tension field stress, f_{yw} acting on the web.

15.6.3.4 *Bolted/Riveted construction*

For girders in exposed situations and which do not have flange plates for their entire length, the top edge of the web plate shall be flush with or above the angles, and the bottom edge of the web plate shall be flush with or set back from the angles.

15.6.3.5 *Welded construction*

The gap between the web plates and flange plates shall be kept to a minimum and for fillet welds shall not exceed 1 mm at any point before welding.

15.6.4 *Webs*

15.6.4.1 *Effective sectional area of web of plate girder*

The effective cross sectional area shall be taken as the full depth of the web plate multiplied by the thickness.

NOTE — Where webs are varied in thickness in the depth of the section by the use of tongue plates or the like, or where the proportion of the web included in the flange area is 25 percent or more of the overall depth, the above approximation is not permissible and the maximum shear stress shall be computed on theory.

15.6.4.2 *Splices in webs*

Splices and cutouts for service ducts in the webs should preferably not be located at points of maximum shear force and heavy concentrated loads.

Splices in the webs of the plate girders and rolled sections shall be designed to resist the shears and moments at the spliced section (see Annex F).

In riveted or bolted construction, splice plates shall be provided on each side of the web. In welded construction, web splices shall preferably be made with complete penetration butt welds.

15.6.4.3 Where additional plates are required to augment the strength of the web, they shall be placed on each side of the web and shall be equal in thickness. The proportion of shear force assumed to be resisted by these plates shall be limited by the amount of horizontal shear which they can transmit to the flanges through their fastenings, and such reinforcing plates and their fastenings shall be carried up to the points at which the flange without the additional plates is adequate.

15.7 Stiffener Design

15.7.1 *General*

15.7.1.1 When the web of a member acting alone (that is, without stiffeners) proves inadequate, stiffeners for meeting the following requirements should be provided:

- a) *Intermediate transverse web stiffener* — To improve the buckling strength of a slender web due to shear (see **15.7.2**).
- b) *Load carrying stiffener* — To prevent local buckling of the web due to concentrated loading (see **15.7.3** and **15.7.5**).
- c) *Bearing stiffener* — To prevent local crushing of the web due to concentrated loading (see **15.7.4** and **15.7.6**).
- d) *Torsion stiffener* — To provide torsional restraint to beams and girders at supports (see **15.7.9**).
- e) *Diagonal stiffener* — To provide local reinforcement to a web under shear and bearing (see **15.7.7**).
- f) *Tension stiffener* — To transmit tensile forces applied to a web through a flange (see **15.7.8**).

The same stiffeners may perform more than one function and their design should comply with the requirements of all the functions for which designed.

15.7.1.2 *Outstand of web stiffeners*

Unless the outer edge is continuously stiffened, the outstand from the face of the web should not exceed $20t_{q\varepsilon}$.

When the outstand of web stiffener is between $14t_{q\varepsilon}$ and $20t_{q\varepsilon}$, then the stiffener design should be on the basis of a core section with an outstand of only $14t_{q\varepsilon}$, where t_q is the thickness of the stiffener.

15.7.1.3 *Stiff bearing length*

The stiff bearing length of any element, b_1 , is that length which cannot deform appreciably in bending. To determine b_1 , the dispersion of load through a steel bearing element should be taken as 45° through solid material, such as bearing plates, flange plates, etc (see Fig.15).

15.7.1.4 *Eccentricity*

Where a load or reaction is applied eccentric to the centerline of the web or where the centroid of the stiffener does not lie on the centerline of the web, the resulting eccentricity of loading should be accounted for in the design of the stiffener.

15.7.1.5 *Buckling resistance of stiffeners*

The buckling resistance F_{qd} should be based on the design compressive stress f_{cd} (see **14.1.2.1**) of a strut (curve c), the radius of gyration being taken about the axis parallel to the web. The effective section is the full area or core area of the stiffener (see **15.7.1.2**) together with an effective length of web on each side of the centerline of the stiffeners, limited to 20 times the web thickness. The design strength used should be the minimum value obtained for buckling about the web or the stiffener.

The effective length for intermediate transverse stiffeners used in calculating the buckling resistance, F_{qd} , should be taken as 0.7 times the length, L of the stiffener.

The effective length for load carrying web stiffeners used in calculating the buckling resistance, F_{xd} , assumes that the flange through which the load or reaction is applied is effectively restrained against lateral movement relative to the other flange, the effective length should be taken as:

- a) $KL = 0.7L$, when flange is restrained against rotation in the plane of the stiffener (by other structural elements), and
- b) $KL = L$, when flange is not so restrained

where

L = length of the stiffener.

If the load or reaction is applied to the flange by a compression member, then unless effective lateral restraint is provided at that point, the stiffener should be designed as part of the compression member applying the load, and the connection between the column and beam flange shall be checked for the effects of the strut action.

FIG. 15 STIFF BEARING LENGTH, b_1

15.7.2 Design of Intermediate Transverse Web Stiffeners**15.7.2.1 General**

Intermediate transverse stiffeners may be provided on one or both sides of the web.

15.7.2.2 Spacing

Spacing of intermediate stiffeners, where provided, shall comply with **15.6.1** depending on the thickness of the web.

15.7.2.3 Outstand of stiffeners

The outstand of the stiffeners should comply with **15.7.1.2**.

15.7.2.4 Minimum stiffeners

Transverse web stiffeners not subject to external loads or moments should have a second moment of area, I_s about the centerline of the web, if stiffeners are on both sides of the web and about the face of the web, if single stiffener on only one side of the web is used such that:

$$\begin{aligned} \text{if } c/d &\geq \sqrt{2}, & I_s &\geq 0.75 d t_w^3, \text{ and} \\ \text{if } c/d &< \sqrt{2}, & I_s &\geq \frac{1.5 d^3 t_w^3}{c^2} \end{aligned}$$

where

d = depth of the web;

t_w = minimum required web thickness for spacing using tension field action, as given in **15.4.2.1**; and

c = actual stiffener spacing.

15.7.2.5 Buckling check on intermediate transverse web stiffeners

Stiffeners not subjected to external loads or moments should be checked for a stiffener force:

$$F_q = V - V_{cr} / \gamma_{m0} \leq F_{qd}$$

where

F_{qd} = design resistance of the intermediate stiffeners;

V = factored shear force adjacent to the stiffener; and

V_{cr} = shear buckling resistance of the web panel designed without using tension field action as given in **15.4.2.2 a**).

Stiffeners subject to external loads and moments should meet the conditions for load carrying web stiffeners in **15.7.3**. In addition they should satisfy the following interaction expression:

$$\frac{F_q - F_x}{F_{qd}} + \frac{F_x}{F_{xd}} + \frac{M_q}{M_{yq}} \leq 1$$

where

- F_q = stiffener force given above;
- F_{qd} = design resistance of an intermediate web stiffener corresponding to buckling about an axis parallel to the web (see **15.7.1.5**);
- F_x = external load or reaction at the stiffener;
- F_{xd} = design resistance of a load carrying stiffener corresponding to buckling about axis parallel to the web (see **15.7.1.5**);
- M_q = moment on the stiffener due to eccentrically applied load and transverse load, if any; and
- M_{yq} = yield moment capacity of the stiffener based on its elastic modulus about its centroidal axis parallel to the web.

If $F_q < F_x$, then $(F_q - F_x)$ should be taken as zero;

15.7.2.6 Connection of intermediate stiffeners to web

Intermediate transverse stiffeners not subject to external loading should be connected to the web so as to withstand a shear between each component of the stiffener and the web (in kN/mm) of not less than:

$$t_w^2 / (5b_s)$$

where

- t_w = web thickness, in mm; and
- b_s = outstand width of the stiffener, in mm.

For stiffeners subject to external loading, the shear between the web and the stiffener due to such loading has to be added to the above value.

Stiffeners not subject to external loads or moments may terminate clear of the tension flange and in such a situation the distance cut short from the line of the weld should not be more than $4t_w$.

15.7.3 Load Carrying Stiffeners

15.7.3.1 Web check

Load carrying web stiffeners should be provided where compressive forces applied through a flange by loads or reactions exceed the buckling strength, F_{cdw} , of the unstiffened web, calculated using the following:

The effective length of the web for evaluating the slenderness ratio is calculated as in **15.7.1.5**. The area of cross section is taken as $(b_1 + n_1) t_w$.

where

b_1 = width of stiff bearing on the flange (see **15.7.1.3**), and
 n_1 = dispersion of the load through the web at 45°, to the level of half the depth of the cross-section.

The buckling strength of this web about axis parallel to the web is calculated as given in **14.1.2.1**, using curve 'c'.

15.7.4 Bearing Stiffeners

Bearing stiffeners should be provided for webs where forces applied through a flange by loads or reactions exceeding the local capacity of the web at its connection to the flange, F_w , given by:

$$F_w = (b_1 + n_2) t_w f_{yw} / \gamma_{m0}$$

where

b_1 = stiff bearing length (see **15.7.1.3**),
 n_2 = length obtained by dispersion through the flange to the web junction at a slope of 1:2.5 to the plane of the flange,
 t_w = thickness of the web, and
 f_{yw} = yield stress of the web.

15.7.5 Design of Load Carrying Stiffeners

15.7.5.1 Buckling check

The external load or reaction, F_x on a stiffener should not exceed the buckling resistance, F_{xd} of the stiffener as given in **15.7.1.5**.

Where the stiffener also acts as an intermediate stiffener it should be checked for the effect of combined loads in accordance with **15.7.2.5**.

15.7.5.2 Bearing check

Load carrying web stiffeners should also be of sufficient size that the bearing strength of the stiffener, F_{psd} , given below is not less than the load transferred, F_x

$$F_{psd} = A_q f_{yq} / (0.8 \gamma_{m0}) \geq F_x$$

where

F_x = external load or reaction,
 A_q = area of the stiffener in contact with the flange, and
 f_{yq} = yield stress of the stiffener.

15.7.6 Design of Bearing Stiffeners

Bearing stiffeners should be designed for the applied load or reaction less the local capacity of the web as given in **15.7.4**. Where the web and the stiffener material are of different strengths the lesser value should be assumed to calculate the capacity of the web and the stiffener. Bearing stiffeners should project nearly as much as the overhang of the flange through which load is transferred.

15.7.7 Design of Diagonal Stiffeners

Diagonal stiffeners should be designed to carry the portion of the applied shear and bearing that exceeds the capacity of the web.

Where the web and the stiffener are of different strengths, the value for design should be taken as given in **15.7.6**.

15.7.8 Design of Tension Stiffeners

Tension stiffeners should be designed to carry the portion of the applied load or reaction less the capacity of the web as given in **15.7.4** for bearing stiffeners.

Where the web and the stiffener are of different strengths, the value for design should be taken as given in **15.7.6**.

15.7.9 Torsional Stiffeners

Where bearing stiffeners are required to provide torsional restraint at the supports of the beam, they should meet the following criteria:

- a) Conditions of **15.7.4**, and
- b) Second moment of area of the stiffener section about the centerline of the web, I_s should be such that:

$$I_s \geq 0.34 \alpha_s D^3 T_{cf}$$

where

- $\alpha_s = 0.006$ for $L_{LT} / r_y \leq 50$;
 $= 0.3 / (L_{LT} / r_y)$ for $50 < L_{LT} / r_y \leq 100$;
 $= 30 / (L_{LT} / r_y)^2$ for $L_{LT} / r_y > 100$;
 D = Overall depth of beam at support,
 T_{cf} = Maximum thickness of compression flange in the span under consideration,
 KL = Laterally unsupported effective length of the compression flange of the beam, and
 r_y = Radius of gyration of the beam about the minor axis.

15.7.10 Connection to Web of Load Carrying and Bearing Stiffeners — Stiffeners, which resist loads or reactions applied through a flange, should be connected to the web by sufficient welds or fasteners to transmit a design force equal to the lesser of,

- a) tension capacity of the stiffener; and
- b) sum of the forces applied at the two ends of the stiffener when they act in the same direction or the larger of the forces when they act in opposite directions.

Stiffeners, which do not extend right across the web, should be of such length that the shear stress in the web due to the design force transmitted by the stiffener does not exceed the shear strength of the web. In addition, the capacity of the web beyond the end of the stiffener should be sufficient to resist the applied force.

15.7.11 Connection to Flanges

15.7.11.1 In tension

Stiffeners required to resist tension should be connected to the flange transmitting the load by continuous welds or non-slip fasteners.

15.7.11.2 In compression

Stiffeners required to resist compression should either be fitted against the loaded flange or connected by continuous welds or non-slip fasteners.

The stiffener should be fitted against or connected to both flanges when,

- a) a load is applied directly over a support; or
- b) it forms the end stiffener of a stiffened web; or
- c) it acts as a torsion stiffener.

15.7.12 Hollow Sections

Where concentrated loads are applied to hollow sections consideration should be given to local stresses and deformations and the section reinforced as necessary.

15.7.13 Horizontal Stiffeners

Where horizontal stiffeners are used in addition to vertical stiffeners, they shall be as follows:

- a) One horizontal stiffener shall be placed on the web at a distance from the compression flange equal to $1/5$ of the distance from the compression flange angle, plate or tongue plate to the neutral axis when the thickness of the web is less than the limits specified in **15.6.1**. The stiffener shall be designed so that I_s is not less than $4ct_w^3$ where I_s and t_w are as defined in **15.7.2.4** and c is the actual distance between the vertical stiffeners;
- b) A second horizontal stiffener (single or double) shall be placed at the neutral axis of the girder when the thickness of the web is less than the limit specified in **15.6.1**. This stiffener shall be designed so that I_s is not less than $d_2 t_w^3$ where I_s and t_w are as defined in **15.7.2.4** and d_2 is twice the clear distance from the compression flange angles, plates or tongue plates to the neutral axis;
- c) Horizontal web stiffeners shall extend between vertical stiffeners, but need not be continuous over them; and
- d) Horizontal stiffeners may be in pairs arranged on each side of the web, or single located on one side of the web.

15.8 Box Girders

The design and detailing of box girders shall be such as to give full advantage of its higher load carrying capacity. Box girder shall be designed in accordance with specialist literature. The diaphragms and horizontal stiffeners should conform to **15.7.12** and **15.7.13**.

15.8.1 All diaphragms shall be connected so as to transfer the resultant shears to the web and flanges.

15.8.2 Where the concentrated or moving load does not act directly on top of the web, the local effect shall be considered in the design of flanges and the diaphragms.

15.9 Purlins and Sheeting Rails (Girts)

15.9.1 All purlins shall be designed in accordance with the requirements for beams as specified in **15.2.1** and **15.2.2**. The limitations of bending stress based on lateral instability of the compression flange shall be considered if the purlin does not receive adequate support from bracings and sheathings in the plane of compression flange. In any case the maximum bending moment shall not exceed the values specified in **15.2.1**. The calculated deflections should not exceed those permitted for the type of roof cladding used, as specified in **12.6.1**. In calculating the bending moment, advantage may be taken of the continuity of the purlin over supports. The bending about the two axes shall be

determined separately and checked according to the biaxial bending requirements specified under **16**.

15.10 Bending in a Non-Principal Plane

15.10.1 When the flexural deflection of a member is constrained to a non-principal plane by lateral restraints preventing lateral deflection, then the force exerted by the restraints shall be determined, and the principal axes bending moments acting on the member shall be calculated from these forces and applied forces, by a rational analysis. The combined effect of bending about the principal axes shall satisfy the requirements given under **16**.

15.10.2 When the deflections of a member loaded in a non-principal plane are unconstrained; the principal axes bending moments shall be calculated by a rational analysis. The combined effect of bending about the principal axes shall satisfy the requirements given under **16**.

16 MEMBER SUBJECTED TO COMBINED FORCES

16.1 General

This Section governs the design of members subjected to combined forces, such as shear force and bending, axial force and bending, or shear force, axial force and bending.

16.2 Combined Shear and Bending

16.2.1 No reduction in moment capacity of the section is necessary as long as the cross section is not subjected to high shear force (factored value of applied shear force is less than or equal to 60 percent of the shear strength of the section as given in **15.4**). The moment capacity may be taken as, M_d (see **15.2**) without any reduction.

16.2.2 When the factored value of the applied shear force is high (exceeds the limit specified in **16.2.1**), the factored moment of the section should be less than the moment capacity of the section under higher shear force, M_{dv} , calculated as given below:

a) *Plastic or compact section*

$$M_{dv} = M_d - \beta (M_d - M_{td}) \leq 1.2 Z_e f_y / \gamma_{m0}$$

where

$$\beta = (2 V / V_d - 1)^2,$$

M_d = plastic design moment of the whole section disregarding high shear force effect (see **15.2.1.2**) considering web buckling effects (see **15.2.1.1**),

V = factored applied shear force as governed by web yielding or web buckling,

V_d = design shear strength as governed by web yielding or web buckling (see **15.4.1** or **9.4.2**),

M_{fd} = plastic design strength of the area of the cross section excluding the shear area, considering partial safety factor γ_{m0} , and

Z_e = elastic section modulus of the whole section.

b) *Semi-compact section*

$$M_{dv} = Z_e f_y / \gamma_{m0}$$

16.3 Combined Axial Force and Bending Moment

Under combined axial force and bending moment, section strength as governed by material failure and member strength as governed by buckling failure shall be checked in accordance with **16.3.1** and **16.3.2** respectively.

16.3.1 Section Strength

16.3.1.1 Plastic and compact sections

In the design of members subjected to combined axial force (tension or compression) and bending moment, the following should be satisfied:

$$\left(\frac{M_y}{M_{ndy}} \right)^{\alpha_1} + \left(\frac{M_z}{M_{ndz}} \right)^{\alpha_2} \leq 1.0$$

Conservatively, the following equation may also be used under combined axial force and bending moment:

$$\frac{N}{N_d} + \frac{M_y}{M_{dy}} + \frac{M_z}{M_{dz}} \leq 1.0$$

where

M_y, M_z = factored applied moments about the minor and major axis of the cross section, respectively;

M_{ndy}, M_{ndz} = design reduced flexural strength under combined axial force and the respective uniaxial moment acting alone (see **16.3.1.2**);

N = factored applied axial force (Tension, T or Compression, P);

N_d = design strength in tension, T_d as obtained from **12** or in compression due to yielding given by $N_d = A_g f_y / \gamma_{m0}$;

M_{dy}, M_{dz} = design strength under corresponding moment acting alone (see **15.2**);

A_g = gross area of the cross section;
 α_1, α_2 = constants as given in Table 17; and
 γ_{m0} = partial factor of safety in yielding.

16.3.1.2 For plastic and compact sections without bolts holes, the following approximations may be used for evaluating M_{ndy} and M_{ndz} :

a) *Plates*

$$M_{nd} = M_d (1 - n^2)$$

b) *Welded I or H-sections*

$$M_{ndy} = M_{dy} \left[1 - \left(\frac{n-a}{1-a} \right)^2 \right] \leq M_{dy} \quad \text{where } n \geq a$$

$$M_{ndz} = M_{dz} (1 - n) / (1 - 0.5a) \leq M_{dz}$$

where

$$n = N / N_d \text{ and } a = (A - 2 b t_f) / A \leq 0.5$$

c) *For standard I or H sections*

$$M_{ndz} = 1.11 M_{dz} (1 - n) \leq M_{dz}$$

$$\begin{aligned}
 &\text{for } n \leq 0.2, & M_{ndy} &= M_{dy} \\
 &\text{for } n > 0.2, & M_{ndy} &= 1.56 M_{dy} (1 - n) (n + 0.6) \\
 & & M_{ndz} &= 1.11 M_{dz} (1 - n) \leq M_{dz}
 \end{aligned}$$

d) *For rectangular hollow sections and welded box sections*

When the section is symmetric about both axes and without bolt holes

$$\begin{aligned}
 M_{ndy} &= M_{dy} (1 - n) / (1 - 0.5a_f) \leq M_{dy} \\
 M_{ndz} &= M_{dz} (1 - n) / (1 - 0.5a_w) \leq M_{dz}
 \end{aligned}$$

where

$$a_w = (A - 2 b t_f) / A \leq 0.5$$

$$a_f = (A - 2 h t_w) / A \leq 0.5$$

e) *Circular hollow tubes without bolt holes*

$$M_{nd} = 1.04 M_d (1 - n^{1.7}) \leq M_d$$

Table 17 Constants α_1 and α_2
(Clause 16.3.1.1)

SI No. (1)	Section (2)	α_1 (3)	α_2 (4)
i)	I and Channel	$5n \geq 1$	2
ii)	Circular tubes	2	2
iii)	Rectangular tubes	$1.66/(1 - 1.13n^2) \leq 6$	$1.66/(1 - 1.13n^2) \leq 6$
iv)	Solid rectangles	$1.73 + 1.8n^3$	$1.73 + 1.8n^3$

NOTE — $n = N/N_d$

16.3.1.3 Semi-compact section

In the absence of high shear force (see **16.2.1**), semi-compact section design is satisfactory under combined axial force and bending, if the maximum longitudinal stress under combined axial force and bending, f_x satisfies the following criteria:

$$f_x \leq f_y / \gamma_{m0}$$

For cross section without holes, the above criteria reduces to,

$$\frac{N}{N_d} + \frac{M_y}{M_{dy}} + \frac{M_z}{M_{dz}} \leq 1.0$$

where

N_d , M_{dy} , M_{dz} are as defined in **16.3.1.1**.

16.3.2 Overall Member Strength

Members subjected to combined axial force and bending moment shall be checked for overall buckling failure as given in this section.

16.3.2.1 Bending and axial tension

The reduced effective moment, M_{eff} , under tension and bending calculated as given below, should not exceed the bending strength due to lateral torsional buckling, M_d (see **15.2.2**),

$$M_{\text{eff}} = [M - \psi T Z_{\text{ec}} / A] \leq M_d$$

where

M, T = factored applied moment and tension, respectively;

A = area of cross section;

Z_{ec} = elastic section modulus of the section with respect to extreme compression fibre; and

$\psi = 0.8$, if T and M can vary independently, or otherwise
= 1.0.

16.3.2.2 Bending and axial compression

Members subjected to combined axial compression and biaxial bending shall satisfy the following interaction relationships:

$$\frac{P}{P_{\text{dy}}} + K_y \frac{C_{\text{my}} M_y}{M_{\text{dy}}} + K_{\text{LT}} \frac{M_z}{M_{\text{dz}}} \leq 1.0$$

$$\frac{P}{P_{\text{dz}}} + 0.6 K_y \frac{C_{\text{my}} M_y}{M_{\text{dy}}} + K_z \frac{C_{\text{mz}} M_z}{M_{\text{dz}}} \leq 1.0$$

where

$C_{\text{my}}, C_{\text{mz}}$ = equivalent uniform moment factor as per Table 18;

P = applied axial compression under factored load;

M_y, M_z = maximum factored applied bending moments about y and z-axis of the member, respectively;

$P_{\text{dy}}, P_{\text{dz}}$ = design strength under axial compression as governed by buckling about minor (y) and major (z) axis respectively;

$M_{\text{dy}}, M_{\text{dz}}$ = design bending strength about y (minor) or z (major) axis considering laterally unsupported length of the cross section [see 15];

$K_y = 1 + (\lambda_y - 0.2)n_y \leq 1 + 0.8 n_y$;

$K_z = 1 + (\lambda_z - 0.2)n_z \leq 1 + 0.8 n_z$, and

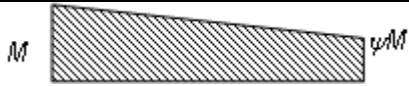

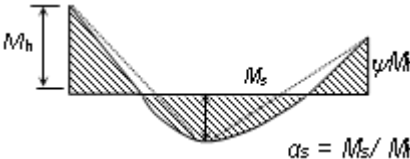

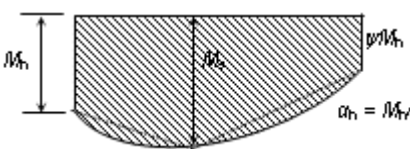

$$K_{\text{LT}} = 1 - \frac{0.1 \lambda_{\text{LT}} n_y}{(C_{\text{mLT}} - 0.25)} \geq 1 - \frac{0.1 n_y}{(C_{\text{mLT}} - 0.25)}$$

where

n_y, n_z = ratio of actual applied axial force to the design axial strength for buckling about the y and z-axis, respectively, and

C_{mLT} = Equivalent uniform moment factor for lateral torsional buckling as per Table 18 corresponding to the actual moment gradient between lateral supports against torsional deformation in the critical region under consideration.

Table 18 Equivalent Uniform Moment Factor
(Clause 10.3.2.2)

Bending Moment Diagram (1)	Range (2)	C_{my}, C_{mz}, C_{mLT}		
		Uniform Loading (3)	Concentrated Load (4)	
	$-1 \leq \psi \leq 1$	$0.6 + 0.4 \psi \geq 0.4$		
	$0 \leq \alpha_s \leq 1$	$-1 \leq \psi \leq 1$	$0.2 + 0.8 \alpha_s \geq 0.4$	
	$-1 \leq \alpha_s \leq 0$	$0 \leq \psi \leq 1$	$0.1 - 0.8 \alpha_s \geq 0.4$	$-0.8 \alpha_s \geq 0.4$
		$-1 \leq \psi \leq 0$	$0.1(1-\psi) - 0.8 \alpha_s \geq 0.4$	$0.2(1-\psi) - 0.8 \alpha_s \geq 0.4$
	$0 \leq \alpha_h \leq 1$	$-1 \leq \psi \leq 1$	$0.95 - 0.05 \alpha_h$	$0.90 + 0.10 \alpha_h$
	$-1 \leq \alpha_h \leq 0$	$0 \leq \psi \leq 1$	$0.95 + 0.05 \alpha_h$	$0.90 + 0.10 \alpha_h$
		$-1 \leq \psi \leq 0$	$0.95 + 0.05 \alpha_h (1+2 \psi)$	$0.90 + 0.1 \alpha_h (1+2 \psi)$

For members with sway buckling mode, the equivalent uniform moment factor $C_{my} = C_{mz} = 0.9$.

C_{my}, C_{mz}, C_{mLT} shall be obtained according to the bending moment diagram between the relevant braced points

Moment factor	Bending axis	Points braced in direction
C_{my}	Z-Z	Y-Y
C_{mz}	Y-Y	Z-Z
C_{mLT}	Z-Z	Z-Z

17 CONNECTIONS

17.1 General

17.1.1 This Section deals with the design and detailing requirements for joints between members. Connection elements consist of components such as cleats, gusset plates, brackets, connecting plates and connectors such as rivets, bolts, pins, and welds. The connections in a structure shall be designed so as to be consistent with the assumptions made in the analysis of the structure and comply with the requirements specified in this section. Connections shall be capable of transmitting the calculated design actions.

17.1.2 Where members are connected to the surface of a web or the flange of a section, the ability of the web or the flange to transfer the applied forces locally should be checked and where necessary, local stiffening provided.

17.1.3 Ease of fabrication and erection should be considered in the design of connections. Attention should be paid to clearances necessary for field erection, tolerances, tightening of fasteners, welding procedures, subsequent inspection, surface treatment and maintenance.

17.1.4 The ductility of steel assists the distribution of forces generated within a joint. Effects of residual stresses and stresses due to tightening of fasteners and normal tolerances of fit-up need not therefore be considered in connection design, provided ductile behaviour is ensured.

17.1.5 In general, use of different forms of fasteners to transfer the same force shall be avoided. However, when different forms of fasteners are used to carry a shear load or when welding and fasteners are combined, then one form of fastener shall be normally designed to carry the total load. Nevertheless, fully tensioned friction grip bolts may be designed to share the load with welding, provided the bolts are fully tightened to develop necessary pretension after welding.

17.1.6 The partial safety factor in the evaluation of design strength of connections shall be taken as given in Table 5.

17.2 Location Details of Fasteners

17.2.1 Clearances for Holes for Fasteners

Bolts may be located in standard size, over size, short slotted or long slotted hole, as follows.

- a) *Standard clearance hole* — Except where fitted bolts, bolts in low-clearance or oversize holes are specified, the diameter of standard clearance holes for fasteners shall be as given in Table 19.
- b) *Oversize hole* — Holes of size larger than the standard clearance holes, as given in Table 19 may be used in slip resistant connections and hold down bolted connections, only where specified, provided the oversize
- c) Holes in the outer ply is covered by a cover plate of sufficiently large size and thickness and having a hole not larger than the standard clearance hole (and hardened washer in slip resistant connections).
- d) *Short and long slots* — Slotted holes of size larger than the standard clearance hole, as given in Table 19 may be used in slip resistant connections and hold down

bolted connections, only where specified, provided the oversize holes in the outer ply is covered by a cover plate of sufficiently large size and thickness and having a hole of size not larger than the standard clearance hole (and hardened washer in slip resistant connection).

Table 19 Clearances for Fastener Holes
(Clause 17.2.1)

SI No.	Nominal Size of Fastener, d mm	Size of the Hole = Nominal Diameter of the Fastener + Clearances mm			
		Standard clearance in diameter and Width of Slot	Over Size Clearance in Diameter	Clearance in the Length of the Slot	
				Short Slot	Long Slot
(1)	(2)	(3)	(4)	(5)	(6)
i)	12 – 14	1.0	3.0	4.0	$2.5 d$
ii)	16 – 22	2.0	4.0	6.0	$2.5 d$
iii)	24	2.0	6.0	8.0	$2.5 d$
iv)	Larger than 24	3.0	8.0	10.0	$2.5 d$

17.2.2 Minimum Spacing

The distance between centres of fasteners shall not be less than 2.5 times the nominal diameter of the fastener.

17.2.3 Maximum Spacing

17.2.3.1 The distance between the centres of any two adjacent fasteners shall not exceed $32t$ or 300 mm, whichever is less, where t is the thickness of the thinner plate.

17.2.3.2 The distance between the centres of two adjacent fasteners (pitch) in a line lying in the direction of stress, shall not exceed $16t$ or 200 mm, whichever is less, in tension members and $12t$ or 200 mm, whichever is less, in compression members; where t is the thickness of the thinner plate. In the case of compression members wherein forces are transferred through butting faces, this distance shall not exceed 4.5 times the diameter of

the fasteners for a distance equal to 1.5 times the width of the member from the butting faces.

17.2.3.3 The distance between the centres of any two consecutive fasteners in a line adjacent and parallel to an edge of an outside plate shall not exceed 100 mm plus $4t$ or 200 mm, whichever is less, in compression and tension members; where t is the thickness of the thinner outside plate.

17.2.3.4 When fasteners are staggered at equal intervals and the gauge does not exceed 75 mm, the spacing specified in **17.2.3.2** and **17.2.3.3** between centres of fasteners may be increased by 50 percent, subject to the maximum spacing specified in **17.2.3.1**.

17.2.4 *Edge and End Distances*

17.2.4.1 The edge distance is the distance at right angles to the direction of stress from the centre of a hole to the adjacent edge. The end distance is the distance in the direction of stress from the centre of a hole to the end of the element.

In slotted holes, the edge and end distances should be measured from the edge or end of the material to the centre of its end radius or the centre line of the slot, whichever is smaller. In oversize holes, the edge and end distances should be taken as the distance from the relevant edge/end plus half the diameter of the standard clearance hole corresponding to the fastener, less the nominal diameter of the oversize hole.

17.2.4.2 The minimum edge and end distances from the centre of any hole to the nearest edge of a plate shall not be less than 1.7 times the hole diameter in case of sheared or hand-flame cut edges; and 1.5 times the hole diameter in case of rolled, machine-flame cut, sawn and planed edges.

17.2.4.3 The maximum edge distance to the nearest line of fasteners from an edge of any un-stiffened part should not exceed $12 t\varepsilon$, where $\varepsilon = (250/f_y)^{1/2}$ and t is the thickness of the thinner outer plate. This would not apply to fasteners interconnecting the components of back to back tension members. Where the members are exposed to corrosive influences, the maximum edge distance shall not exceed 40 mm plus $4t$, where t is the thickness of thinner connected plate.

17.2.5 *Tacking Fasteners*

17.2.5.1 In case of members covered under **17.2.4.3**, when the maximum distance between centres of two adjacent fasteners as specified in **17.2.4.3** is exceeded, tacking fasteners not subjected to calculated stress shall be used.

17.2.5.2 Tacking fasteners shall have spacing in a line not exceeding 32 times the thickness of the thinner outside plate or 300 mm, whichever is less. Where the plates are exposed to the weather, the spacing in line shall not exceed 16 times the thickness of the

thinner outside plate or 200 mm, whichever is less. In both cases, the distance between the lines of fasteners shall not be greater than the respective pitches.

17.2.5.3 All the requirements specified in **17.2.5.2** shall generally apply to compression members, subject to the stipulations given under **14** affecting the design and construction of compression members.

17.2.5.4 In tension members [see **13**] composed of two flats, angles, channels or tees in contact back to back or separated back to back by a distance not exceeding the aggregate thickness of the connected parts, tacking fasteners with solid distance pieces shall be provided at a spacing in line not exceeding 1 000 mm.

17.2.5.5 For compression members covered under **14**, tacking fasteners in a line shall be spaced at a distance not exceeding 600 mm.

17.2.6 *Countersunk Heads*

For countersunk heads, one-half of the depth of the countersinking shall be neglected in calculating the length of the fastener in bearing in accordance with **17.3.3**. For fasteners in tension having countersunk heads, the tensile strength shall be reduced by 33.3 percent. No reduction is required to be made in shear strength calculations.

17.3 Bearing Type Bolts

17.3.1 *Effective Areas of Bolts*

17.3.1.1 Since threads can occur in the shear plane, the area A_e for resisting shear should normally be taken as the net tensile stress area, A_n of the bolts. For bolts where the net tensile stress area is not defined, A_n shall be taken as the area at the root of the threads.

17.3.1.2 Where it can be shown that the threads do not occur in the shear plane, A_e may be taken as the cross section area, A_s at the shank.

17.3.1.3 In the calculation of thread length, allowance should be made for tolerance and thread run off.

17.3.2 A bolt subjected to a factored shear force (V_{sb}) shall satisfy the condition

$$V_{sb} \leq V_{db}$$

where V_{db} is the design strength of the bolt, taken as the smaller of the value as governed by shear, V_{dsb} (see **17.3.3**) and bearing, V_{dpb} (see **17.3.4**).

17.3.3 *Shear Capacity of Bolt*

The design strength of the bolt, V_{dsb} as governed by shear strength is given by:

$$V_{dsb} = V_{nsb} / \gamma_{mb}$$

where

V_{nsb} = nominal shear capacity of a bolt, calculated as follows:

$$V_{nsb} = \frac{f_u}{\sqrt{3}} (n_n A_{nb} + n_s A_{sb})$$

where

- f_u = ultimate tensile strength of a bolt;
- n_n = number of shear planes with threads intercepting the shear plane;
- n_s = number of shear planes without threads intercepting the shear plane;
- A_{sb} = nominal plain shank area of the bolt; and
- A_{nb} = net shear area of the bolt at threads, may be taken as the area corresponding to root diameter at the thread.

17.3.3.1 Long joints

When the length of the joint, l_j of a splice or end connection in a compression or tension element containing more than two bolts (that is, the distance between the first and last rows of bolts in the joint, measured in the direction of the load transfer) exceeds $15d$ in the direction of load, the nominal shear capacity (see **17.3.2**), V_{db} shall be reduced by the factor β_{ij} , given by:

$$\begin{aligned} \beta_{ij} &= 1.075 - l_j / (200 d) \quad \text{but } 0.75 \leq \beta_{ij} \leq 1.0 \\ &= 1.075 - 0.005(l_j / d) \end{aligned}$$

where

d = Nominal diameter of the fastener.

NOTE — This provision does not apply when the distribution of shear over the length of joint is uniform, as in the connection of web of a section to the flanges.

17.3.3.2 Large grip lengths

When the grip length, l_g (equal to the total thickness of the connected plates) exceeds 5 times the diameter, d of the bolts, the design shear capacity shall be reduced by a factor β_g , given by:

$$\beta_g = 8d / (3d + l_g) = 8 / (3 + l_g/d)$$

β_g shall not be more than β_{ij} given in **17.3.3.1**. The grip length, l_g shall in no case be greater than $8d$.

17.3.3.3 Packing plates

The design shear capacity of bolts carrying shear through a packing plate in excess of 6 mm shall be decreased by a factor, β_{pk} given by:

$$\beta_{pk} = (1 - 0.012 5 t_{pk})$$

where

t_{pk} = Thickness of the thicker packing, in mm.

17.3.4 Bearing Capacity of the Bolt

The design bearing strength of a bolt on any plate, V_{dpb} as governed by bearing is given by:

$$V_{dpb} = V_{npb} / \gamma_{mb}$$

where

V_{npb} = Nominal bearing strength of a bolt
 $= 2.5 k_b d t f_u$

where

k_b is smaller of $\frac{e}{3d_0}$, $\frac{p}{3d_0} - 0.25$, $\frac{f_{ub}}{f_u}$, 1.0;

e, p = end and pitch distances of the fastener along bearing direction;

d_0 = diameter of the hole;

f_{ub}, f_u = Ultimate tensile stress of the bolt and the ultimate tensile stress of the plate, respectively;

d = nominal diameter of the bolt; and

t = summation of the thicknesses of the connected plates experiencing bearing stress in the same direction, or if the bolts are countersunk, the thickness of the plate minus one half of the depth of countersinking.

The bearing resistance (in the direction normal to the slots in slotted holes) of bolts in holes other than standard clearance holes may be reduced by multiplying the bearing resistance obtained as above, V_{npb} , by the factors given below:

- a) Over size and short slotted holes – 0.7, and
- b) Long slotted holes – 0.5.

NOTE — The block shear of the edge distance due to bearing force may be checked as given in **12.4**.

17.3.5 Tension Capacity

A bolt subjected to a factored tensile force, T_b shall satisfy,

$$T_b \leq T_{db}$$

where

$$T_{db} = T_{nb} / \gamma_{mb}$$

T_{nb} = nominal tensile capacity of the bolt, calculated as:

$$T_{nb} = 0.90 f_{ub} A_n < f_{yb} A_{sb} (\gamma_{mb} / \gamma_{m0})$$

where

f_{ub} = ultimate tensile stress of the bolt,

f_{yb} = yield stress of the bolt,

A_n = net tensile stress area as specified in the appropriate Indian Standard (for bolts where the tensile stress area is not defined, A_n shall be taken as the area at the bottom of the threads), and

A_{sb} = shank area of the bolt.

17.3.6 Bolt Subjected to Combined Shear and Tension

A bolt required to resist both design shear force (V_{sd}) and design tensile force (T_b) at the same time shall satisfy,

$$\left(\frac{V_{sb}}{V_{db}} \right)^2 + \left(\frac{T_b}{T_{db}} \right)^2 \leq 1.0$$

where

V_{sb} = factored shear force acting on the bolt,

V_{db} = design shear capacity (see 17.3.2),

T_b = factored tensile force acting on the bolt, and

T_{db} = design tension capacity (see 17.3.5).

17.4 Friction Grip Type Bolting

17.4.1 In friction grip type bolting, initial pretension in bolt (usually high strength) develops clamping force at the interfaces of elements being joined. The frictional resistance to slip between the plate surfaces subjected to clamping force opposes slip due to externally applied shear. Friction grip type bolts and nuts shall conform to the accepted standard [6-6A(38)]. Their installation procedures shall conform to good practice [6-6A(15)].

17.4.2 Where slip between bolted plates cannot be tolerated at working loads/ strength limit states loads (slip critical connections), the requirements of 17.4.3 shall be satisfied at service and strength limit states loads, respectively. However, the requirements of 17.4.4 shall be satisfied by all connections at the strength limit states.

17.4.3 Slip Resistance

Design for friction type bolting, where slip resistance is required at factored design force V_{sf} , shall satisfy the following:

$$V_{sf} \leq V_{dsf}$$

where

$$V_{dsf} = V_{nsf} / \gamma_{mf}$$

V_{nsf} = nominal shear capacity of a bolt as governed by slip for friction type connection, calculated as follows:

$$V_{nsf} = \mu_f n_e K_h F_o$$

where

μ_f = coefficient of friction (slip factor) as specified in Table 20 ($\mu_f \leq 0.55$);

n_e = number of effective interfaces offering frictional resistance to slip;

K_h = 1.0 for fasteners in clearance holes,

= 0.85 for fasteners in oversized and short slotted holes and for fasteners in long slotted holes loaded perpendicular to the slot,

= 0.7 for fasteners in long slotted holes loaded parallel to the slot;

γ_{mf} = 1.10 (if slip resistance is designed at service load),

= 1.25 (if slip resistance is designed at ultimate load);

F_o = minimum bolt tension (proof load) at installation and may be taken as $A_{nb} f_o$,

A_{nb} = net area of the bolt at threads, and

f_o = proof stress (= 0.70 f_{ub}).

NOTE — V_{nsf} may be evaluated at a service load or ultimate load using appropriate partial safety factors, depending upon whether slip resistance is required at service load or ultimate load.

Table 20 Typical Average Values for Coefficient of Friction (μ_f)
(Clause 17.4.3)

SI No.	Treatment of Surface	Coefficient of friction, μ_f
(1)	(2)	(3)
i)	Surfaces not treated	0.20
ii)	Surfaces blasted with short or grit with any loose rust removed, no pitting	0.50
iii)	Surfaces blasted with shot or grit and hot-dip galvanized	0.10
iv)	Surfaces blasted with shot or grit and spray-metallized with zinc (thickness 50 – 70 μm)	0.25

v)	Surfaces blasted with shot or grit and painted with ethyl zinc silicate coat (thickness 30 – 60 μm)	0.30
vi)	Sand blasted surface, after light rusting	0.52
vii)	Surfaces blasted with shot or grit and painted with ethyl zinc silicate coat (thickness 60 – 80 μm)	0.30
viii)	Surfaces blasted with shot or grit and painted with alkali zinc silicate coat (thickness 60 – 80 μm)	0.30
ix)	Surface blasted with shot or grit and spray metallized with aluminium (thickness > 50 μm)	0.50
x)	Clean mill scale	0.33
xi)	Sand blasted surface	0.48
xii)	Red lead painted surface	0.1

17.4.3.1 Long Joints

The provision for the long joints in **17.3.3.1** shall apply to friction grip connections also.

17.4.4 Capacity after Slipping

When friction type bolts are designed not to slip only under service loads, the design capacity at ultimate load may be calculated as per bearing type connection (see **17.3.2** and **17.3.3**).

NOTE — The block shear resistance of the edge distance due to bearing force may be checked as given in **13.4**.

17.4.5 Tension Resistance

A friction bolt subjected to a factored tension force (T_f) shall satisfy:

$$T_f \leq T_{df}$$

where

$$T_{df} = T_{nf} / \gamma_{mf}$$

T_{nf} = nominal tensile strength of the friction bolt, calculated as:

$$T_{nf} = 0.9 f_{ub} A_n \leq f_{yb} A_{sb} (\gamma_{m1} / \gamma_{m0})$$

where

f_{ub} = ultimate tensile stress of the bolt;

A_n = net tensile stress area as specified in various parts of the accepted standard [6-6A(39)] (for bolts where the tensile stress area is not defined, A_n shall be taken as the area at the root of the threads);

A_{sb} = shank area of the bolt; and

γ_{mf} = partial factor of safety.

17.4.6 Combined Shear and Tension

Bolts in a connection for which slip in the serviceability limit state shall be limited, which are subjected to a tension force, T , and shear force, V , shall satisfy:

$$\left(\frac{V_{sf}}{V_{df}}\right)^2 + \left(\frac{T_f}{T_{df}}\right)^2 \leq 1.0$$

where

V_{sf} = applied factored shear at design load;

V_{df} = design shear strength;

T_f = externally applied factored tension at design load; and

T_{df} = design tension strength.

17.4.7 Where prying force, Q as illustrated in Fig. 16 shall be calculated as given below and added to the tension in the bolt:

$$Q = \frac{l_v}{2l_e} \left[T_e - \frac{\beta \eta f_o b_e t^4}{27l_e l_v^2} \right]$$

where

l_v = distance from the bolt centreline to the toe of the fillet weld or to half the root radius for a rolled section, and

l_e = distance between prying force and bolt centreline and is the minimum of either the end distance or the value given by:

$$l_e = 1.1 t \sqrt{\frac{\beta f_o}{f_y}}$$

where

β = 2 for non pre-tensioned bolt and 1 for pre-tensioned bolt,

η = 1.5,

b_e = effective width of flange per pair of bolts,

f_o = proof stress in consistent units, and

t = thickness of the end plate.

FIG. 16 COMBINED PRYING FORCE AND TENSION

17.5 Welds and Welding

17.5.1 General

Requirements of welds and welding shall conform to the accepted standards [6-6A(40)], as appropriate.

17.5.1.1 End returns

Fillet welds terminating at the ends or sides of parts should be returned continuously around the corners for a distance of not less than twice the size of the weld, unless it is impractical to do so. This is particularly important on the tension end of parts carrying bending loads.

17.5.1.2 Lap joint

In the case of lap joints, the minimum lap should not be less than four times the thickness of the thinner part joined or 40 mm, whichever is more. Single end fillet should be used only when lapped parts are restrained from openings. When end of an element is connected only by parallel longitudinal fillet welds, the length of the weld along either edge should not be less than the transverse spacing between longitudinal welds.

17.5.1.3 A single fillet weld should not be subjected to moment about the longitudinal axis of the weld.

17.5.2 Size of Weld

17.5.2.1 The size of normal fillets shall be taken as the minimum weld leg size. For deep penetration welds, where the depth of penetration beyond the root run is a minimum of 2.4 mm, the size of the fillet should be taken as the minimum leg size plus 2.4 mm.

17.5.2.2 For fillet welds made by semi-automatic or automatic processes, where the depth of penetration is considerably in excess of 2.4 mm, the size shall be taken considering actual depth of penetration subject to agreement between the purchaser and the contractor.

17.5.2.3 The size of fillet welds shall not be less than 3 mm. The minimum size of the first run or of a single run fillet weld shall be as given in Table 21, to avoid the risk of cracking in the absence of preheating.

17.5.2.4 The size of butt weld shall be specified by the effective throat thickness.

17.5.3 Effective Throat Thickness

17.5.3.1 The effective throat thickness of a fillet weld shall not be less than 3 mm and shall generally not exceed $0.7t$, or $1.0t$ under special circumstances, where t is the thickness of the thinner plate of elements being welded.

17.5.3.2 For the purpose of stress calculation in fillet welds joining faces inclined to each other, the effective throat thickness shall be taken as K times the fillet size, where K is a constant, depending upon the angle between fusion faces, as given in Table 22.

Table 21 Minimum Size of First Run or of a Single Run Fillet Weld
(Clause 17.5.2.3)

SI No.	Thickness of Thicker Part mm		Minimum Size mm
	Over	Up to and Including	
(1)	(2)	(3)	(4)
i)	–	10	3
ii)	10	20	5
iii)	20	32	6
iv)	32	50	8 of first run 10 for minimum size of weld

NOTES

- 1 When the minimum size of the fillet weld given in the table is greater than the thickness of the thinner part, the minimum size of the weld should be equal to the thickness of the thinner part. The thicker part shall be adequately preheated to prevent cracking of the weld.

- 2 Where the thicker part is more than 50 mm thick, special precautions like preheating should be taken.

Table 22 Values of K for Different Angles Between Fusion Faces
(Clause 17.5.3.2)

Angle Between Fusion Faces	60°– 90°	91° - 100°	101° - 106°	107° - 113°	114° - 120°
Constant, K	0.70	0.65	0.60	0.55	0.50

17.5.3.3 The effective throat thickness of a complete penetration butt weld shall be taken as the thickness of the thinner part joined, and that of an incomplete penetration butt weld shall be taken as the minimum thickness of the weld metal common to the parts joined, excluding reinforcements.

17.5.4 Effective Length or Area of Weld

17.5.4.1 The effective length of fillet weld shall be taken as only that length which is of the specified size and required throat thickness. In practice the actual length of weld is made of the effective length shown in drawing plus two times the weld size, but not less than four times the size of the weld.

17.5.4.2 The effective length of butt weld shall be taken as the length of the continuous full size weld, but not less than four times the size of the weld.

17.5.4.3 The effective area of a plug weld shall be considered as the nominal area of the hole in the plane of the faying surface. These welds shall not be designed to carry stresses.

17.5.4.4 If the maximum length l_j of the side welds transferring shear along its length exceeds 150 times the throat size of the weld, t_t , the reduction in weld strength as per the long joint (see **17.5.7.3**) should be considered. For flange to web connection, where the welds are loaded for the full length, the above limitation would not apply.

17.5.5 Intermittent Welds

17.5.5.1 Unless otherwise specified, the intermittent fillet welding shall have an effective length of not less than four times the weld size, with a minimum of 40 mm.

17.5.5.2 The clear spacing between the effective lengths of intermittent fillet weld shall not exceed 12 and 16 times the thickness of thinner plate joined, for compression and tension joint, respectively, and in no case be more than 200 mm.

17.5.5.3 Unless otherwise specified, the intermittent butt weld shall have an effective length of not less than four times the weld size and the longitudinal space between the effective length of welds shall not be more than 16 times the thickness of the thinner part joined. The intermittent welds shall not be used in positions subject to dynamic, repetitive and alternating stresses.

17.5.6 Weld Types and Quality

For the purpose of this code, weld shall be fillet, butt, slot or plug or compound welds. Welding electrodes shall conform to the accepted standard [6-6A(18)].

17.5.7 Design Stresses in Welds

17.5.7.1 Shop welds

17.5.7.1.1 Fillet welds – Design strength of a fillet weld, f_{wd} shall be based on its throat area and shall be given by:

$$f_{wd} = f_{wn} / \gamma_{mw}$$

where

$$f_{wn} = f_u / \sqrt{3},$$

f_u = smaller of the ultimate stress of the weld or of the parent metal, and

γ_{mw} = partial safety factor (see Table 5).

17.5.7.1.2 Butt welds

Butt welds shall be treated as parent metal with a thickness equal to the throat thickness, and the stresses shall not exceed those permitted in the parent metal.

17.5.7.1.3 Slot or plug welds

The design shear stress on slot or plug welds shall be as per **17.5.7.1.1**.

17.5.7.2 Site welds

The design strength in shear and tension for site welds made during erection of structural members shall be calculated according to **17.5.7.1** but using a partial safety factor γ_{mw} of 1.5.

17.5.7.3 Long joints

When the length of the welded joint, l_j of a splice or end connection in a compression or tension element is greater than $150 t$, the design capacity of weld (see **17.5.7.1.1**), f_{wd} shall be reduced by the factor:

$$\beta_{lw} = 1.2 - \frac{0.2l_j}{150t_t} \leq 1.0$$

where

l_j = length of the joint in the direction of the force transfer, and
 t_t = throat size of the weld.

17.5.8 Fillet Weld Applied to the Edge of a Plate or Section

17.5.8.1 Where a fillet weld is applied to the square edge of a part, the specified size of the weld should generally be at least 1.5 mm less than the edge thickness in order to avoid washing down of the exposed corner (see Fig. 17A).

17.5.8.2 Where the fillet weld is applied to the rounded toe of a rolled section, the specified size of the weld should generally not exceed 3/4 of the thickness of the section at the toe (see Fig. 17B).

17.5.8.3 Where the size specified for a fillet weld is such that the parent metal will not project beyond the weld, no melting of the outer cover or covers shall be allowed to occur to such an extent as to reduce the throat thickness (see Fig. 18)

FIG. 17 FILLET WELDS ON SQUARE EDGE OF PLATE OR ROUND TOE OF ROLLED SECTION

FIG. 18 FULL SIZE FILLET WELD APPLIED TO THE EDGE OF A PLATE OR SECTION

17.5.8.4 When fillet welds are applied to the edges of a plate or section in members subject to dynamic loading, the fillet weld shall be of full size with its leg length equal to the thickness of the plate or section, with the limitations specified in **17.5.8.3**.

17.5.8.5 End fillet weld, normal to the direction of force shall be of unequal size with a throat thickness not less than $0.5t$, where t is the thickness of the part, as shown in Fig. 19. The difference in thickness of the welds shall be negotiated at a uniform slope.

17.5.9 Stresses Due to Individual Forces

When subjected to either compressive or tensile or shear force alone, the stress in the weld is given by:

$$f_a \text{ or } q = \frac{P}{t_t l_w}$$

where

f_a = calculated normal stress due to axial force, in N/mm²;

q = shear stress, in N/mm²;

P = force transmitted (axial force N or the shear force Q);

t_t = effective throat thickness of weld, in mm; and

l_w = effective length of weld, in mm.

FIG. 19 END FILLET WELD NORMAL TO DIRECTION OF FORCE

17.5.10 Combination of Stresses

17.5.10.1 Fillet welds

17.5.10.1.1 When subjected to a combination of normal and shear stress, the equivalent stress f_e shall satisfy the following:

$$f_e = \sqrt{f_a^2 + 3q^2} \leq \frac{f_u}{\sqrt{3}\gamma_{mw}}$$

where

f_a = normal stresses, compression or tension, due to axial force or bending moment (see **17.5.9**), and

q = shear stress due to shear force or tension (see **17.5.9**).

17.5.10.1.2 Check for the combination of stresses need not be done for:

- a) Side fillet welds joining cover plates and flange plates, and
- b) Fillet welds where sum of normal and shear stresses does not exceed f_{wd} (see **17.5.7.1.1**).

17.5.10.2 *Butt welds*

17.5.10.2.1 Check for the combination of stresses in butt welds need not be carried out provided that,

- a) butt welds are axially loaded, and
- b) in single and double bevel welds the sum of normal and shear stresses does not exceed the design normal stress, and the shear stress does not exceed 50 percent of the design shear stress.

17.5.10.2.2 *Combined bearing, bending and shear*

Where bearing stress, f_{br} is combined with bending (tensile or compressive), f_b and shear stresses, q under the most unfavorable conditions of loading in butt welds, the equivalent stress, f_e as obtained from the following formula, shall not exceed the values allowed for the parent metal:

$$f_e = \sqrt{f_b^2 + f_{br}^2 + f_b f_{br} + 3q^2}$$

where

f_e = equivalent stress;

f_b = calculated stress due to bending, in N/mm²;

f_{br} = calculated stress due to bearing, in N/mm²; and

q = shear stress, in N/mm².

17.5.11 Where a packing is welded between two members and is less than 6 mm thick, or is too thin to allow provision of adequate welds or to prevent buckling, the packing shall be trimmed flush with the edges of the element subject to the design action and the size of the welds along the edges shall be increased over the required size by an amount

equal to the thickness of the packing. Otherwise, the packing shall extend beyond the edges and shall be fillet welded to the pieces between which it is fitted.

17.6 Design of Connections

Each element in a connection shall be designed so that the structure is capable of resisting the design actions. Connections and adjacent regions of the members shall be designed by distributing the design action effects such that the following requirements are satisfied:

- a) Design action effects distributed to various elements shall be in equilibrium with the design action effects on the connection,
- b) Required deformations in the elements of the connections are within their deformations capacities,
- c) All elements in the connections and the adjacent areas of members shall be capable of resisting the design action effects acting on them, and
- d) Connection elements shall remain stable under the design action effects and deformations.

17.6.1 Connections can be classified as rigid, semi-rigid and flexible for the purpose of analysis and design as per the recommendation in Annex F. Connections with sufficient rotational stiffness may be considered as rigid. Examples of rigid connections include flush end-plate connection and extended end-plate connections. Connections with negligible rotational stiffness may be considered as flexible (pinned). Examples of flexible connections include single and double web angle connections and header plate connections. Where a connection cannot be classified as either rigid or flexible, it shall be assumed to be semi-rigid. Examples of semi-rigid connections include top and seat angle connection and top and seat angle with single/double web angles.

17.6.2 Design shall be on the basis of any rational method supported by experimental evidence. Residual stresses due to installation of bolts or welding normally need not be considered in statically loaded structures. Connections in cyclically loaded structures shall be designed considering fatigue as given under **19**. For earthquake load combinations, the connections shall be designed to withstand the calculated design action effects as specified in **18**.

17.6.3 Beam and column splice shall be designed in accordance with the recommendation given in **F-2** and **F-3**.

17.7 Minimum Design Action on Connection

Connections carrying design action effects, except for lacing connections, connections of sag rods, purlins and girts, shall be designed to transmit the greater of:

- a) the design action in the member; and

- b) The minimum design action effects expressed either as the value or the factor times the member design capacity for the minimum size of member required by the strength limit state, specified as follows:

1) *Connections in rigid construction* – A bending moment of at least 0.5 times the member design moment capacity.

2) *Connections to beam in simple construction* – A shear force of at least 0.15 times the member design shear capacity or 40 kN, whichever is lesser.

3) *Connections at the ends of tensile or compression member* – A force of at least 0.3 times the member design capacity.

4) *Splices in members subjected to axial tension* – A force of at least 0.3 times the member design capacity in tension.

5) *Splices in members subjected to axial compression* – For ends prepared for full contact in accordance with **24.7.1**, it shall be permissible to carry compressive actions by bearing on contact surfaces. When members are prepared for full contact to bear at splices, there shall be sufficient fasteners to hold all parts securely in place. The fasteners shall be sufficient to transmit a force of at least 0.15 times the member design capacity in axial compression.

When members are not prepared for full contact, the splice material and its fasteners shall be arranged to hold all parts in line and shall be designed to transmit a force of at least 0.3 times the member design capacity in axial compression.

In addition, splices located between points of effective lateral support shall be designed for the design axial force, P_d plus a design bending moment, not less than the design bending moment $M_d = P_d l_s / 1000$ where, l_s is the distance between points of effective lateral support.

6) *Splices in flexural members* – A bending moment of 0.3 times the member design capacity in bending. This provision shall not apply to splices designed to transmit shear force only.

A splice subjected to a shear force only shall be designed to transmit the design shear force together with any bending moment resulting from the eccentricity of the force with respect to the centroid of the group.

7) *Splices in members subject to combined actions* – A splice in a member subject to a combination of design axial tension or design axial compression and design bending moment shall satisfy requirements in (4), (5) and (6) above, simultaneously.

17.8 Intersections

Members or components meeting at a joint shall be arranged to transfer the design actions between the parts, wherever practicable, with their centroidal axes meeting at a point. Where there is eccentricity at joints, the members and components shall be designed for the design bending moments which result due to eccentricity.

The disposition of fillet welds to balance the design actions about the centroidal axis or axes for end connections of single angle, double angle and similar type members is not required for statically loaded members but is required for members, connection components subject to fatigue loading.

Eccentricity between the centroidal axes of angle members and the gauge lines for their bolted end connections may be neglected in statically loaded members, but shall be considered in members and connection components subject to fatigue loading.

17.9 Choice of Fasteners

Where slip in the serviceability limit state is to be avoided in a connection, high-strength bolts in a friction-type joint, fitted bolts or welds shall be used.

Where a joint is subjected to impact or vibration, either high strength bolts in a friction type joint or ordinary bolts with locking devices or welds shall be used.

17.10 Connection Components

Connection components (cleats, gusset plates, brackets and the like) other than connectors, shall have their capacities assessed using the provisions of **12**, **13**, **14**, **15** and **16**, as applicable.

17.11 Analysis of a Bolt/Weld Group

17.11.1 Bolt/Weld Group Subject to In-plane Loading

17.11.1.1 General method of analysis

The design force in a bolt/weld or design force per unit length in a bolt/weld group subject to in-plane loading shall be determined in accordance with the following:

- a) The connection plates shall be considered to be rigid and to rotate relative to each other about a point known as the instantaneous centre of rotation of the group.
- b) In the case of a group subject to a pure couple only, the instantaneous centre of rotation coincides with the group centroid. In the case of in-plane shear force applied at the group centroid, the instantaneous centre of the rotation is at infinity and the design force is uniformly distributed throughout the group. In all other

cases, either the results of independent analyses for a pure couple alone and for an in-plane shear force applied at the group centroid shall be superposed, or a recognized method of analysis shall be used.

- c) The design force in a bolt or design force per unit length at any point in the group shall be assumed to act at right angles to the radius from that point to the instantaneous centre, and shall be taken as proportional to that radius.

17.11.2 Bolt/Weld Group Subject to Out-of-Plane Loading

17.11.2.1 General method of analysis

The design force of a bolt in bolt group or design force per unit length in the fillet weld group subject to out-of-plane loading shall be determined in accordance with the following:

- a) Design force in the bolts or per unit length in the fillet weld group resulting from any shear force or axial force shall be considered to be equally shared by all bolts in the group or uniformly distributed over the length of the fillet weld group.
- b) Design force resulting from a design bending moment shall be considered to vary linearly with distance from the relevant centroidal axes. The following shall also be considered:
 - 1) In bearing type of bolt group plates in the compression side of the neutral axis and only bolts in the tension side of the neutral axis may be considered for calculating the neutral axis and second moment of area.
 - 2) In the friction grip bolt group, only the bolts shall be considered in the calculation of neutral axis and second moment of area.
 - 3) The fillet weld group shall be considered in isolation from the connected element; for the calculation of centroid and second moment of the weld length.

17.11.2.2 Alternative analysis

The design force per unit length in a fillet weld/bolt group may alternatively be determined by considering the fillet weld group as an extension of the connected member and distributing the design forces among the welds of the fillet weld group so as to satisfy equilibrium between the fillet weld group and the elements of the connected member.

17.11.3 Bolt/Weld Group Subject to In-plane and Out-of-Plane Loading

17.11.3.1 General method of analysis

The design force in a bolt or per unit length of the weld shall be determined by the superposition of analysis for in-plane and out-of-plane cases discussed in **17.11.1** and **17.11.2**.

17.11.3.2 *Alternative analysis*

The design force in a bolt or per unit length in the fillet weld group may alternatively be determined by considering the fillet weld group as an extension of the connected member and proportioning the design force per bolt or unit length in the weld group to satisfy equilibrium between the bolt/weld group and the elements of the connected member.

Force calculated in the most stressed bolt or highest force per unit length of the weld shall satisfy the strength requirements of **17.3**, **17.4** or **17.5**, as appropriate.

17.12 Lug Angles

17.12.1 Lug angles connecting outstanding leg of a channel-shaped member shall, as far as possible, be disposed symmetrically with respect to the section of the member.

17.12.2 In the case of angle members, the lug angles and their connections to the gusset or other supporting member shall be capable of developing a strength not less than 20 percent in excess of the force in the outstanding leg of the member, and the attachment of the lug angle to the main angle shall be capable of developing a strength not less than 40 percent in excess of the force in the outstanding leg of the angle.

17.12.3 In the case of channel members and the like, the lug angles and their connection to the gusset or other supporting member shall be capable of developing a strength of not less than 10 percent in excess of the force not accounted for by the direct connection of the member, and the attachment of the lug angles to the member shall be capable of developing 20 percent in excess of that force.

17.12.4 In no case shall fewer than two bolts, rivets or equivalent welds be used for attaching the lug angle to the gusset or other supporting member.

17.12.5 The effective connection of the lug angle shall, as far as possible terminate at the end of the member connected, and the fastening of the lug angle to the main member shall preferably start in advance of the direct connection of the member to the gusset or other supporting member.

17.12.6 Where lug angles are used to connect an angle member, the whole area of the member shall be taken as effective notwithstanding the requirements given under **13**.

18 DESIGN AND DETAILING FOR EARTHQUAKE EFFECTS

18.1 General

Earthquake is a 'displacement loading' on a structure. This implies that 'displacements' are 'imposed' under a structure during earthquake shaking and 'forces' are induced in it. Thus, a structure is allowed to be designed to have lesser strength capacity than that required if it were to remain elastic. And, only chosen types of damage are permitted to be accrued in select components of a structure during strong earthquake shaking.

Thus, reliance is placed on the nonlinear response of a structure, especially on its deformation and ductility capacities. These must be achieved by adopting special design and detailing practices. Therefore, steel frames shall be so designed and detailed as to give them stability, and adequate stiffness, strength, and ductility capacities to resist severe earthquake shaking without collapse in all earthquake zones mentioned in **5** of Part 6 'Structural Design' Section 1 'Loads, Forces and Effects' of the Code.

18.1.1 As per **5** of Part 6 'Structural Design' Section 1 'Loads, Forces and Effects' of the Code., based on the relative severity of the negative consequences (that is, losses of life and livestock, disruption to lifeline infrastructure, losses of property and harm to natural environment) in the event of their failure, the structures are categorized for the purposes of design to resist earthquake effects into:

- (a) Normal Structures,
- (b) Important Structures,
- (c) Critical Structures, and
- (d) Special Structures,

Therefore, the requirements of applicable structural systems, stability, stiffness, strength, and ductility increase from normal to special structures, and from earthquake zone II to earthquake zone VI (see **5** of Part 6 'Structural Design' Section 1 'Loads, Forces and Effects' of the Code).

18.1.2 Steel frames required to resist earthquake effects in all earthquake zones shall satisfy the requirements specified in IS 18168. Frames are classified into two types, one which have minimal inelastic deformation and ductility capacities, called Ordinary Frames, and one with higher deformation and ductility capacities, called Special Frames. For important, critical or special structures and those in regions of moderate and high seismicity, that is earthquake zones III, IV, V and VI, only special frames are permitted to be used (refer **5** of Part 6 'Structural Design' Section 1 'Loads, Forces and Effects' of the Code); design and detailing specifications of these special frames are provided in IS 18168.

18.1.3 In earthquake zone II and for normal and important structures, Ordinary Frames, namely Ordinary Moment Frames (OMF) and Ordinary Concentrically Braced Frames (OCBF), are permitted to be used. In design and detailing of OMFs and OCBFs, specific requirements of this Section shall be satisfied along with other provisions of this Standard, in addition to the earthquake demand and design criteria requirements of **5** of Part 6 'Structural Design' Section 1 'Loads, Forces and Effects' of the Code.

18.1.4 Frames, which are a part of the gravity load resisting system and are not intended to resist the lateral earthquake forces, need not satisfy the requirements of this section, provided they can accommodate the resulting earthquake shaking induced deformation without premature failure.

18.1.5 Load Combinations

Additional load combinations for earthquake resistant design shall be as per **5** of Part 6 'Structural Design' Section 1 'Loads, Forces and Effects' of the Code.

18.2 Connections, Joints and Fasteners

18.2.1 All bolts used in frames designed to resist earthquake effects shall be fully tensioned high strength friction grip (HSFG) bolts or turned and fitted bolts.

18.2.2 All welds used in frames designed to resist earthquake effects shall be complete penetration butt welds, except in column splices, which shall conform to **18.5.2**.

18.2.3 Bolted joints shall be designed not to share load in combination with welds on the same faying surface.

18.3 Ordinary Moment Frames (OMFs)

Ordinary moment frames (OMFs) of structural steel shall be designed to satisfy the requirements of this section.

18.3.1 Basis of Design

Ordinary moment frames designed in accordance with these provisions are expected to possess limited inelastic deformation capacity through flexural yielding of the beams, panel zones, and columns.

18.3.2 Analysis

When two moment frames oriented in orthogonal directions intersect, the possibility of beam yielding in both orthogonal directions simultaneously shall be considered in the estimation of design demand on the common column.

18.3.3 Member Requirements

The requirements specified hereunder shall be satisfied by the component or member.

18.3.3.1 Beams

Beam cross-section shall be plastic or compact, as defined in **10.8.2**.

18.3.3.2 Columns

Column cross-section shall be plastic or compact, as defined in **10.8.2**.

18.3.4 System Requirements

It is preferable to plan buildings to have independent lateral load resisting moment frames in the vertical plane along each principal plan direction. Also, the requirements given hereunder shall be satisfied by the building system.

18.3.4.1 Beam-to-column connections

Beam-to-column connections may be rigid or semi-rigid moment connections, but shall satisfy the following criteria:

- a) Rigid moment connections shall be designed to withstand a moment of at least 1.2 times of either the full plastic moment of the connected beam or the maximum moment that can be delivered by the beam to the joint due to the induced weakness at the ends of the beam, whichever is less.
- b) Semi-rigid connections shall be designed and to withstand either a moment of at least 0.5 times the full plastic moment of the connected beam or the maximum moment that can be delivered by the system, whichever is less. The design moment shall be achieved within a rotation of 0.01 radians. The information given in Annex F may be used for checking.
- c) The stiffness and strength of semi-rigid connections shall be accounted for in the design and the overall stability of the frame shall be ensured.

- d) The rigid and semi-rigid connections shall be designed to withstand a shear resulting from the load combination $1.2DL + 0.5LL$ plus the shear corresponding to the design moment defined in **(a)** and **(b)**, respectively.
- e) In rigid fully welded connections, continuity plates of thickness equal to or greater than the thickness of the beam flange shall be provided and welded to the column flanges and web.

18.3.4.2 Column to beam strength ratio

At a beam–column joint, strong column weak beam design shall be adopted, suitably accounting for the reduction in moment capacity of columns due to axial load.

18.4 Ordinary Concentrically Braced Frames (OCBF)

Ordinary concentrically braced frames (OCBFs) of structural steel shall be designed to satisfy the requirements given hereunder. Collector beams that connect OCBF braces shall be considered to be part of OCBF.

18.4.1 Basis of Design

In OCBFs, members shall be concentrically connected. But eccentricities less than the beam depth are permitted if the resulting member and connection forces are addressed in the design, and the eccentricities do not change the expected source of inelastic deformation capacity of the building. OCBF designed in accordance with these provisions are expected to provide limited inelastic deformation capacity primarily through brace buckling under compression and yielding of the brace in tension.

18.4.2 Analysis

The following shall be satisfied in the analysis of OCBFs.

18.4.2.1 The axial force demand on the braces shall be determined considering earthquake effects specified in **5** of Part 6 ‘Structural Design’ Section 1 ‘Loads, Forces and Effects’ of the Code. The analysis shall ensure that the axial compression induced in the brace does not exceed the design strength of the brace in axial compression as per **14.1.2**).

18.4.3 Member Requirements

The requirements specified hereunder shall be satisfied by the component or member.

18.4.3.1 Braces

- a) The cross-section can be plastic, compact or semi-compact, but not slender, as defined in **10.8.2**.
- b) The slenderness ratio shall not exceed 120.
- c) The required compressive strength shall not exceed 0.8 times P_d , where P_d is the design strength in axial compression (see **14.1.2**).
- d) For all built-up braces, the spacing of tack fasteners shall be such that the unfavorable slenderness ratio of individual element, between such fasteners, shall not exceed 0.4 times the governing slenderness ratio of the brace itself. Bolted connections shall be avoided within the middle one-fourth of the clear brace length (0.25 times the length in the middle).
- e) They shall be designed so that gross area yielding (see **13.2**) and not the net area rupture (see **13.3**) would govern the design tensile strength.

18.4.4 System Requirements

The requirements specified hereunder shall be applicable.

18.4.4.1 Diagonal and X-braced frames

Diagonal and X-braced frames are permitted to be used in OCBF.

18.4.4.2 V- and inverted V-braced frame

V- and inverted V-braced frames are permitted to be used in OCBF. In such systems, the beams that are intersected by braces away from beam-to-column connections shall satisfy the following requirements:

- a) Beams shall be continuous between columns and adequately braced to prevent lateral torsional buckling; and
- b) As a minimum, one set of lateral braces in plan is required at the point of intersection of the V type (or inverted V-type) braces with the beams in the frames, unless the

beam has sufficient out-of-plane strength and stiffness to ensure stability between adjacent brace points.

18.4.4.3 *K-braced frames*

K-braced frames shall not be used in SCBF.

18.4.4.4 *Continuity of Load Path*

For applying the clauses in this standard, the following definitions shall be used:

- a) A line of braces is as a single line, or parallel lines with a plan offset of 10 percent or less of the building dimension perpendicular to the line of braces interconnected adequately through rigid diaphragm.
- b) A diaphragm is rigid if the maximum lateral displacement measured from the chord of the deformed shape at any point of the diaphragm is less than 1.2 times the average displacement of the entire diaphragm.

18.4.4.5 *Lateral Force Distribution*

Braces shall be provided in alternate directions along each line of braces. Along any line of braces, braces shall be provided such that for lateral loading in either direction, tension braces resist between 30 and 70 percent of the total horizontal load.

18.4.4.6 *Bracing connections*

The following shall be applicable:

- a) End connections in bracings shall be designed to withstand the minimum of the following:
 - 1) A tensile force in the bracing equal to $1.2f_yA_g$ of the bracing member being connected;
 - 2) Force in the brace due to design load combinations; and
 - 3) Maximum force that can be transferred to the brace by the system.
- b) The connection shall be checked for tension rupture and block shear.
- c) The connection shall be designed to withstand a moment of 1.2 times the full plastic moment of the braced section about the buckling axis.
- d) Gusset plates shall be checked for buckling out-of-their plane.

18.5 Industrial Structures

18.5.1 Single storey industrial buildings with frame height to span ratio less than 1.0 and with regular configuration need not meet the ductility requirements of other types of frames specified in **18.3**, **18.4** or in **IS 18168**, provided they satisfy the requirements in **18.5.2** and **18.5.3**.

18.5.2 Braced frames or moment frames are permitted as lateral force resisting system and shall be designed using $R = 1.5$.

18.5.3 Connections in lateral force resisting systems shall be designed for full member capacity except those in earthquake zones V and VI, where the connections shall be designed for 50 percent extra force.

19 FATIGUE

19.1 General

Structure and structural elements subject to loading that could lead to fatigue failure shall be designed against fatigue as given in this section. This shall however not cover the following:

- a) Corrosion fatigue,
- b) Low cycle (high stress) fatigue,
- c) Thermal fatigue,
- d) Stress corrosion cracking,
- e) Effects of high temperature ($> 150^{\circ}\text{C}$), and
- f) Effects of low temperature ($<$ brittle transition temperature).

19.1.1 For the purpose of design against fatigue, different details (of members and connections) are classified under different fatigue class. The design stress range corresponding to various number of cycles, are given for each fatigue class. The requirements of this Section shall be satisfied with, at each critical location of the structure subjected to cyclic loading, considering relevant number of cycles and magnitudes of stress range expected to be experienced during the life of the structure.

19.2 Design

19.2.1 Reference Design Condition

The standard S-N curves for each detail category are given for the following conditions:

- a) Detail is located in a redundant load path, wherein local failure at that detail alone will not lead to overall collapse of the structure.

- b) Nominal stress history at the local point in the detail is estimated/evaluated by a conventional method without taking into account the local stress concentration effects due to the detail.
- c) Load cycles are not highly irregular.
- d) Details are accessible for and subject to regular inspection.
- e) Structure is exposed to only mildly corrosive environment as in normal atmospheric condition and suitably protected against corrosion (pit depth <1 mm).
- f) Structure is not subjected to temperature exceeding 150 °C.
- g) Transverse fillet or butt weld connects plates of thickness not greater than 25 mm.

19.2.1.1 Thickness correction factor

The values obtained from the standard S-N curve shall be modified by a capacity reduction factor μ_t , when plates greater than 25 mm in thickness are joined together by transverse fillet or butt welding, given by:

$$\mu_t = (25/t_p)^{0.25} \leq 1.0$$

where

t_p = actual thickness of the thicker plate being joined, in mm.

No thickness correction is necessary when full penetration butt weld reinforcements are machined flush and proved free of defect through nondestructive testing.

19.2.1.2 Necessity for fatigue assessment

- a) Fatigue assessment is not normally required for building structures except as follows:
 - 1) Members supporting lifting or rolling loads,
 - 2) Member subjected to repeated stress cycles from vibrating machinery,
 - 3) Members subjected to wind induced oscillations of a large number of cycles in life, and
 - 4) Members subjected to crowd induced oscillations of a large number of cycles in life.
- b) No fatigue assessment is necessary if the following conditions are satisfied.

- 1) The highest normal stress range f_{\max} satisfies:

$$f_{\max} \leq 27 \mu_r / \gamma_{mf}$$

- 2) The highest shear stress range τ_{\max} satisfies:

$$\tau_{\max} \leq 67 \mu_r / \gamma_{mf}$$

- 3) The total number of actual stress cycles N_{sc} , satisfies:

$$N_{SC} \leq 5 \times 10^6 \left(\frac{27 \mu_r}{\gamma_{mf} f_{eq}} \right)^3$$

where

f_{eq} = equivalent constant amplitude stress range, in MPa, given by:

$$f_{eq} = \left[\frac{\sum_{i=1}^{r5} n_i f_i^3 + \sum_{j=r5}^r n_j f_j^5}{n} \right]^{1/3}$$

where

$$n = \sum_{i=1}^r n_i$$

f_i, f_j = stress ranges falling above and below the f_m , the stress range corresponding to the detail at 5×10^6 number of life cycles.

19.2.2 Design Spectrum

19.2.2.1 Stress evaluation

Design stress shall be determined by elastic analysis of the structure to obtain stress resultants and the local stresses may be obtained by a conventional stress analysis method. The normal and shear stresses shall be determined considering all design actions on the members, but excluding stress concentration due to the geometry of the detail. The stress concentration effect is accounted for in detail category classification (see Table 26). The stress concentration, however, not characteristic of the detail shall be accounted for separately in the stress calculation.

In the fatigue design of trusses made of members with open sections, in which the end connections are not pinned, the stresses due to secondary bending moments shall be taken into account, unless the slenderness ratio (KL/r), of the member is greater than 40.

In the determination of stress range at the end connections between hollow sections, the effect of connection stiffness and eccentricities may be disregarded, provided,

- the calculated stress range is multiplied by appropriate factor given in Table 24(a) in the case of circular hollow section connections and Table 24(b) in the case of rectangular hollow section connections.
- the design throat thickness of fillet welds in the joints is greater than the wall thickness of the connected member.

19.2.2.2 Design stress spectrum

In the case of loading events producing non-uniform stress range cycle, the stress spectrum may be obtained by a rational method, such as 'rain flow counting' or an equivalent method.

**Table 24(a) Multiplying Factors for Calculated Stress Range
(Circular Hollow Sections)**
(Clause 19.2.2.1)

SI No.	Type of Connection		Chords	Verticals	Diagonals
(1)		(2)	(3)	(4)	(5)
i)	Gap connections	{ K type	1.5	1.0	1.3
		{ N type	1.5	1.8	1.4
ii)	Overlap connections	{ K type	1.5	1.0	1.2
		{ N type	1.5	1.65	1.25

(Rectangular Hollow Sections)**
(Clause 19.2.2.1)

SI No.	Types of Joint		Chords	Verticals	Diagonals
(1)	(2)		(3)	(4)	(5)
i)	Gap connections	{ K type	1.5	1.0	1.5
		{ N type	1.5	2.2	1.6
ii)	Overlap connections	{ K type	1.5	1.0	1.3
		{ N type	1.5	2.0	1.4

19.2.3 Partial Safety Factors

19.2.3.1 Partial safety factor for actions and their effects (γ_{fft})

Unless and otherwise the uncertainty in the estimation of the applied actions and their effects demand a higher value, the partial safety factor for loads in the evaluation of stress range in fatigue design shall be taken as 1.0.

19.2.3.2 Partial safety factor for fatigue strength (γ_{mft})

Partial safety factor for strength is influenced by consequences of fatigue damage and level of inspection capabilities.

19.2.3.3 Based on consequences of fatigue failure, component details have been classified as given in the Table 25 and the corresponding partial safety factor for fatigue strength shall be used:

- a) Failsafe structural component/detail is the one where local failure of one component due to fatigue crack does not result in the failure of the structure due to availability of alternate load path (redundant system).
- b) Non-failsafe structural component/detail is the one where local failure of one component leads rapidly to failure of the structure due to its non-redundant nature.

Table 25 Partial Safety Factors for fatigue strength (γ_{mft})
(Clause 19.2.3.3)

SI No.	Inspection and Access	Consequence of Failure	
		Failsafe	Non-failsafe
(1)	(2)	(3)	(4)
i)	Periodic inspection, maintenance and accessibility to detail is good	1.00	1.25
ii)	Periodic inspection, maintenance and accessibility to detail is poor	1.15	1.35

19.3 Detail Category

Tables 26(a) to (d) indicate the classification of different details into various categories for the purpose of assessing fatigue strength. Details not classified in the table may be treated as the lowest detail category of a similar detail, unless superior fatigue strength is proved by testing and/or analysis.

Holes in members and connections subjected to fatigue loading shall not be made,

- a) using punching in plates having thickness greater than 12 mm unless the holes are sub-punched and subsequently reamed to remove the affected material around the punched hole; and
- b) using gas cutting unless the holes are reamed to remove the material in the heat affected zone.

19.4 Fatigue Strength

The fatigue strength of the standard detail for the normal or shear fatigue stress range, not corrected for thickness effects discussed in **19.4.1**, is given below (see also Fig. 22 and Fig. 23):

a) Normal stress range:

1) when $N_{SC} \leq 5 \times 10^6$

$$f_f = f_{fn} \sqrt[3]{5 \times 10^6 / N_{SC}}$$

2) when $5 \times 10^6 \leq N_{SC} \leq 10^8$

$$f_f = f_{fn} \sqrt[5]{5 \times 10^6 / N_{SC}}$$

b) Shear stress:

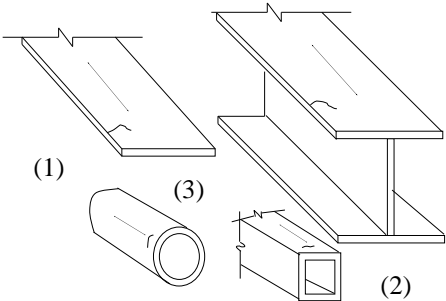

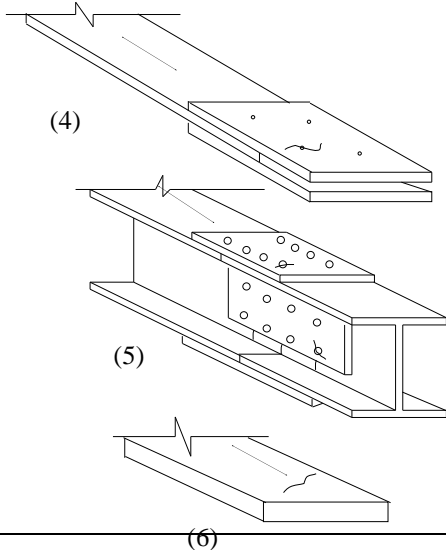

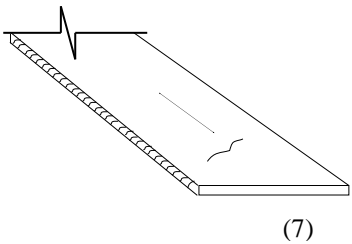

$$\tau_f = \tau_{fn} \sqrt[5]{5 \times 10^6 / N_{SC}}$$

where

f_f, τ_f = design normal and shear fatigue stress range of the detail, respectively, for life cycle of N_{SC} , and

f_{fn}, τ_{fn} = normal and shear fatigue strength of the detail for 5×10^6 cycles, for the detail category (see Table 26).

Table 26(a) Detail Category Classification, Group 1 Non-welded Details (f_{rn})
(Clause 19.3)

NOTE — The arrow indicates the location and direction of the stresses acting in the basic material for which the stress range is to be calculated on a plane normal to the arrow.

19.5 Fatigue Assessment

19.5.1 The design fatigue strength for N_{sc} life cycles (f_{fd} , τ_{fd}) may be obtained from the standard fatigue strength for N_{sc} cycles by multiplying with correction factor, μ_r , for thickness, as mentioned in **19.2.1** and dividing by partial safety factor given in Table 25.

19.5.2 Stress Limitations

19.5.2.1 The maximum (absolute) value of the normal and shear stresses shall never exceed the elastic limit (f_y , τ_y) for the material under cyclic loading.

19.5.2.2 The maximum stress range shall not exceed $1.5 f_y$ for normal stresses and $1.5 f_y / \sqrt{3}$ for the shear stresses under any circumstance.

19.5.2.3 Constant stress range

The actual normal and shear stress range f and τ at a point of the structure subjected to N_{sc} cycles in life shall satisfy:

$$f \leq f_{fd} = \mu_r f_f / \gamma_{mft}$$

$$\tau \leq \tau_{fd} = \mu_r \tau_f / \gamma_{mft}$$

where

μ_r = correction factor (see **19.2.1**),
 γ_{mf} = partial safety factor against fatigue failure, given in Table 25, and
 f_f , τ_f = normal and shear fatigue strength ranges for the actual life cycle, N_{sc} , obtained from **19.4**.

19.5.2.4 Variable stress range

Fatigue assessment at any point in a structure, wherein variable stress ranges f_i or τ_i for n_i number of cycles ($i=1$ to r) are encountered, shall satisfy the following:

a) For normal stress (f):

$$\frac{\sum_{i=1}^{r_5} n_i f_i^3}{5 \times 10^6 (\mu_r f_{fn} / \gamma_{mf})^3} + \frac{\sum_{j=r_5}^r n_j f_j^5}{5 \times 10^6 (\mu_r f_{fn} / \gamma_{mf})^5} \leq 1.0$$

b) For shear stresses (τ):

$$\sum_{i=1}^r n_i \tau_i^5 \leq 5 \times 10^6 (\mu \tau_{fn} / \gamma_{mf})^5$$

Where r_5 is the summation upper limit of all the normal stress ranges (f_i) having magnitude lesser than $(\mu_r f_{fn} / \gamma_{mf})$ for that detail and the lower limit of all the normal stress ranges (f_i) having magnitude greater than $(\mu_r f_{fn} / \gamma_{mf})$ for the detail. In the above summation all normal stress ranges, f_i , and shear stress ranges τ_i having magnitude less than $0.55\mu_r f_{fn}$, and $0.55\mu_r \tau_{fn}$, respectively may be disregarded.

FIG. 22 S-N CURVE FOR NORMAL STRESS

FIG. 23 S-N CURVE FOR SHEAR STRESS

20 DESIGN ASSISTED BY TESTING

20.1 Need for Testing

Testing of structures, members or components of structures is not required when designed in accordance with this standard. Testing may be accepted as an alternative to calculations or may become necessary in special circumstances.

Testing of a structural system, member or component may be required to assist the design in the following cases:

- When the calculation methods available are not adequate for the design of a particular structure, member or component, testing shall be undertaken in place of design by calculation or to supplement the design by calculation;
- Where rules or methods for design by calculation would lead to uneconomical design, experimental verification may be undertaken to avoid conservative design;

- c) When the design or construction is not entirely in accordance with sections of this standard, experimental verification is recommended;
- d) When confirmation is required on the consistency of production of material, components, members or structures originally designed by calculations or testing;
- e) When the actual performance of an existing structure capacity is in question, testing shall be used to confirm it.

20.1.1 Testing of structural system, member or component shall be of the following categories:

- a) *Proof testing* – The application of test loads to a structure, sub-structure, member or connection to ascertain the structural characteristics of only that specific unit.
- b) *Prototype testing* – Testing of structures, sub-structures, members or connections is done to ascertain the structural characteristics of a class of such structures, sub-structures members or connection, which are nominally identical to the units tested.

20.2 Types of Test

20.2.1 Acceptance Test

This is intended as a non-destructive test for confirming structural performance. It should be recognized that the loading applied to certain structures might cause permanent distortions. Such effects do not necessarily indicate structural failure in acceptance test. However, the possibility of their occurrence should be agreed to before testing.

The load for acceptance test, $F_{\text{test,a}}$ shall be determined from:

$$F_{\text{test,a}} = (\text{Self weight}) + (1.15 \times \text{Remainder of the permanent load}) + (1.25 \times \text{Variable load})$$

The assembly shall satisfy the following criteria:

- a) It shall demonstrate substantially linear behaviour under test loading; and
- b) On removal of the test load, the residual deflection shall not exceed 20 percent of the maximum-recorded deflection.

If the above criteria are not satisfied the test may be repeated one more time only, when the assembly shall satisfy the following criteria:

- 1) It shall demonstrate substantially linear behaviour on the second application of test loading, and
- 2) Corresponding recorded residual deflection in the second test shall not exceed 10 percent of the maximum deflection during the test.

20.2.2 Strength Test

Strength test is used to confirm the calculated resistance of a structure or component. Where a number of items are to be constructed to a common design, and one or more prototypes are tested to confirm their strength, the others may be accepted without any additional test, provided they are similar in all relevant respects to the prototype.

Before carrying out the strength test, the specimen should first be subjected to and satisfy the acceptance test. Since the resistance of the assembly under test depends on the material properties, the actual yield strength of all the steel materials in the assembly shall be determined from coupon {test piece as defined in the accepted standard [6-6A(7)]} tests. The mean value of the yield strength, f_{ym} , taken from such tests shall be determined with due regard to the importance of each element in the assembly. The strength test load $F_{test, s}$ (including self weight) shall be determined from:

$$F_{test, s} = \gamma_{mi} F_d (f_{ym} / f_y)$$

where

f_y = characteristic yield stress of the material as assumed in the design;
 F_d = factored design load for the ultimate limit state; and
 γ_{mi} = partial safety factor for the type of failure, as prescribed in this standard.

At this load there shall be no failure by buckling or rupture of any part of the structure or component tested. On removal of the test load, the deflection should decrease by at least 20 percent of the maximum deflection at $F_{test, s}$.

20.2.3 Test to Failure (Ultimate Strength Test)

The objective of a test to failure is to determine the design resistance from the ultimate resistance. In this situation it is still desirable to carry out the acceptance and strength tests, before test to failure.

Not less than three tests shall be carried out on nominally identical specimens. An estimate should be made of the anticipated ultimate resistance as a basis for such tests. During a test to failure, the loading shall first be applied in increments up to the strength test load. Subsequent load increments shall then be determined from consideration of the principal load deflection plot. The test load resistance, $F_{test, R}$ shall be determined as that load at which the specimen is unable to sustain any further increase in load. At this load, gross permanent distortion is likely to have occurred and in some cases such large gross deformation may define the test limit. If the deviation of any individual test result exceeds 10 percent of the mean value obtained for all the three tests, at least three more tests shall be carried out. When the deviation from the mean does not exceed 10 percent of the mean, the design resistance may be evaluated as given below:

- a) When the failure is ductile, the design resistance, F_d may be determined from:

$$F_d = 0.9F_{\text{test,Min}}(f_y / f_{ym}) / \gamma_{m0}$$

where

$F_{\text{test,Min}}$ = minimum test result from the tests to failure,
 f_{ym} = average yield strength as obtained from the material tests, and
 f_y = characteristic yield stress of the grade of steel.

- b) In the case of a sudden (brittle) rupture type failure, the design resistance may be determined from:

$$F_d = 0.9F_{\text{test,Min}}(f_u / f_{um}) / \gamma_{m1}$$

where

f_u = characteristic ultimate stress of the grade of steel used, and
 f_{um} = average ultimate tensile strength of the material obtained from tests.

- c) In the case of a sudden (brittle) buckling type failure, the design resistance shall be determined from:

$$F_d = 0.75F_{\text{test,Min}}(f_y / f_{ym}) / \gamma_{m0}$$

- d) In ductile buckling type failure in which the relevant slenderness λ can be reliably assessed, the design resistance may be determined from:

$$F_d = 0.9F_{\text{test,Min}}[(\chi f_y / \chi_m f_{ym}) / \gamma_{m0}]$$

where

χ = reduction factor for the relevant buckling curve, and
 χ_m = value of χ when the yield strength is f_{ym} .

20.2.4 Check Tests

Where a component or assembly is designed on the basis of strength tests or tests to failure and a production run is carried out of such items, an appropriate number of samples (not less than two) shall be selected from each production batch at random for check tests.

20.2.4.1 The samples shall be carefully examined to ensure that they are similar in all respects to the prototype tested, particular attention being given to the following:

- Dimensions of components and connections,
- Tolerance and workmanship, and

- c) Quality of steel used, checked with reference to mill test certificates.

20.2.4.2 Where it is not possible to determine either the variations or the effect of variations from the prototype, an acceptance test shall be carried out as a check test.

20.2.4.3 In this check test, the deflections shall be measured at the same positions as in the acceptance test of the prototype. The maximum measured deflection shall not exceed 120 percent of the deflection recorded during the acceptance test on the prototype and the residual deflection should not be more than 105 percent of that recorded for the prototype.

20.3 Test Conditions

- a) Loading and measuring devices shall be calibrated in advance.
- b) The design of the test rig shall be such that:
 - 1) Loading system adequately simulates the magnitude and distribution of the loading,
 - 2) It allows the specimen to perform in a manner representative of service conditions,
 - 3) Lateral and torsional restraint, if any, should be representative of those in service,
 - 4) Specimen should be free to deflect under load according to service condition,
 - 5) Loading system shall be able to follow the movements of the specimen without interruption or abnormal restraints,
 - 6) Inadvertent eccentricities at the point of application of the test loads and at the supports are avoided.
- c) Test load shall be applied to the unit at a rate as uniform as practicable.
- d) Deflections should be measured at sufficient points of high movements to ensure that the maximum value is determined.
- e) If the magnitude of stresses in a specimen is to be determined, the strain at the desired location may be measured and the corresponding stress calculated.
- f) Prior to any test, preliminary loading (not exceeding the characteristic values of the relevant loads) may be applied and then removed, in order to set the test specimen on to the test rig.

20.4 Test Loading

20.4.1 Where the self-weight of the specimen is not representative of the actual permanent load in service, allowance for the difference shall be made in the calculation of test loads to be applied.

20.4.2 On the attainment of maximum load for either acceptance or strength tests, this load shall be maintained for at least 1 h. Reading of load and deflection shall be taken at

intervals of 15 min and the loading shall be maintained constant until there is no significant increase in deflection during a 15 min period or until at least 1 h has elapsed.

20.4.3 The test load shall be equal to the design load for the relevant limit state in proof testing.

20.4.4 The test load in prototype testing shall be equal to the design load for the relevant limit state as multiplied by the appropriate factor given in Table 27.

20.5 Criteria for Acceptance

20.5.1 Acceptance for Strength

The test structure, sub-structure, member or connection shall be deemed to comply with the requirements for strength if it is able to sustain the strength test load for at least 15 min.

It shall then be inspected to determine the nature and extent of any damage incurred during the test. The effects of the damage shall be considered and if necessary appropriate repairs to the damaged parts carried out.

20.5.2 Acceptance for Serviceability

The maximum deformation of the structure or member under the serviceability limit state test load shall be within the serviceability limit values appropriate to the structure.

21 DURABILITY

21.1 General

A durable steel structure is one that performs satisfactorily the desired function in the working environment under the anticipated exposure condition during its service life, without deterioration of the cross sectional area and loss of strength due to corrosion.

The material used, the detailing, fabrication, erection and surface protection measures should all address the corrosion protection and durability requirements.

21.2 Requirements for Durability

21.2.1 Shape, Size, Orientation of Members, Connections and Details

The design, fabrication and erection details of exposed structures should be such that good drainage of water is ensured. Standing pool of water, moisture accumulation and rundown of water for extended duration shall be avoided.

The details of connections should ensure that,

- a) all exposed surfaces are easily accessible for inspection and maintenance; and
- b) all surfaces, not so easily accessible are completely sealed against ingress of moisture.

21.2.2 Exposure Condition

21.2.2.1 General environment

The general environment, to which a steel structure is exposed during its working life is classified into five levels of severity, as given in Table 28.

21.2.2.2 Abrasion

Specialist literature may be referred for durability of surfaces exposed to abrasive action as in machinery, conveyor belt support system, storage bins for grains or aggregates.

21.2.2.3 Exposure to sulphate attack

Appropriate coatings may be used when surfaces of structural steel are exposed to concentration of sulphates (SO_3) in soil, ground water, etc.

When exposed to very high sulphate concentrations of more than 2 percent in soil and 5 percent in water, some form of lining such as polyethylene, polychloroprene sheet or surface coating based on asphalt, chlorinated rubber, epoxy or polymethane material should be used to completely avoid access of the solution to the steel surface.

Table 28 Environmental Exposure Conditions

(Clause 21.2.2.1)

SI No.	Environmental Classifications	Exposure Conditions
(1)	(2)	(3)
i)	Mild	Surfaces normally protected against exposure to weather or aggressive condition as in interior of buildings, except when located in coastal areas
ii)	Moderate	Structural steel surfaces: a) Exposed to condensation and rain b) Continuously under water c) Exposed to non-aggressive soil/groundwater d) Sheltered from saturated salt air in coastal areas
iii)	Severe	Structural steel surfaces: a) Exposed to severe frequent rain b) Exposed to alternate wetting and drying c) Severe condensation d) Completely immersed in sea water e) Exposed to saturated salt air in coastal area
iv)	Very severe	Structural steel surface exposed to: a) Sea water spray b) Corrosive fumes c) Aggressive sub-soil or ground water
v)	Extreme	Structural steel surfaces exposed to: a) Tidal zones and splash zones in the sea b) Aggressive liquid or solid chemicals

21.2.3 Corrosion Protection Methods

The methods of corrosion protection are governed by actual environmental conditions as specified in good practices [6-6A(41)]. The main corrosion protection methods are given below:

- a) Controlling the electrode potential,
- b) Inhibitors, and
- c) Inorganic/metal coatings or organic/paint systems.

21.2.4 Surface Protection

21.2.4.1 In the case of mild exposure, a coat of primer after removal of any loose mill scale may be adequate. As the exposure condition becomes more critical, more elaborate surface preparations and coatings become necessary. In case of extreme environmental classification, protection shall be as per specialist literature. Table 29 gives guidance to protection of steelwork for different desired lives.

21.2.4.2 Steel surfaces shall be provided with at least one coat of primer immediately after its surface preparation, such as by sand blasting to remove all mill scale and rust and to expose the steel.

21.2.4.3 Steel without protective coating shall not be stored for long duration in outdoor environment.

21.2.4.4 Surfaces to transfer forces by friction as in HSFG connections shall not be painted. However, it shall be ensured that moisture is not trapped on such surfaces after pre-tensioning of bolts by proper protective measures.

21.2.4.5 Members to be assembled by welding shall not be pre-painted at regions adjacent to the location of such welds. However, after welding, appropriate protective coatings shall be applied in the region, as required by the exposure conditions. If the contact surfaces cannot be properly protected against ingress of moisture by surface coating, they may be completely sealed by appropriate welds.

21.2.4.6 Pre-painted members shall be protected against abrasion of the coating during transportation, handling and erection.

21.2.5 *Special Steels*

Steels with special alloying elements and production process to obtain better corrosion resistance may be used as per specialist literature.

22 FIRE RESISTANCE

22.1 Requirements

The requirements shall apply to steel building elements designed to exhibit a required fire-resistance level (FRL) as per the relevant specifications. The provisions of this section are quite rudimentary and simplistic. Specialist literature for design of steel structures for fire resistance and design based on testing may be necessary for a more comprehensive design of steel buildings to resist fire.

22.1.1 For protected steel members and connections, the thickness of protection material (h_i) shall be greater than or equal to that required to give a period of structural adequacy (PSA) greater than or equal to the required FRL.

22.1.2 For unprotected steel members and connections, the exposed surface area to mass ratio (k_{sm}) shall be less than or equal to that required to give a PSA equal to the required FRL.

22.2 Fire Resistance Level

The required FRL shall be as prescribed in Part 4 'Fire and Life Safety' of the Code as appropriate or in building specifications or as required by the user or the city ordinance. The FRL specified in terms of the duration (in min) of standard fire load without collapse depends upon;

- a) the purpose for which structure is used; and
- b) the time taken to evacuate in case of fire.

22.3 Period of Structural Adequacy (PSA)

22.3.1 The calculation of PSA involves:

- a) Calculation of the strength of the element as a function of temperature of the element and the determination of limiting temperature;
- b) Calculation of the thermal response of the element, that is calculation of the variation of the temperature of the element or the parts of the element with time, when exposed to fire; and
- c) Determination of PSA at which the temperature of the element or parts of the element reaches the limiting temperature.

22.3.2 *Determination of Period of Structural Adequacy*

The period of structural adequacy (PSA) shall be determined using one of the following methods:

- a) *By calculation:*

- 1) determining the limiting temperature of the steel (T_l) in accordance with **22.5**; and
 - 2) determining the PSA as the time (t) (in min) from the start of the test to the time at which the limiting steel temperature is attained, in accordance with **22.6** for protected members and **22.7** for unprotected members.
- b) By direct application of a single test in accordance with **22.8**; or
- c) By calculation of the temperature of the steel member by using a rational method of analysis confirmed by test data or by methods available in specialist literature.

22.4 Variation of Mechanical Properties of Steel with Temperature

22.4.1 Variation of Yield Stress with Temperature

The influence of temperature on the yield stress of steel shall be taken as follows for structures of mild steels and high strength low alloy steels:

$$\frac{f_y(T)}{f_y(20)} = \frac{905 - T}{690} \leq 1.0$$

where,

$f_y(T)$ = yield stress of steel at T °C,
 $f_y(20)$ = yield stress of steel at 20 °C (room temperature), and
 T = temperature of the steel, in °C.

This relationship is shown by curve 1 in Fig. 24.

FIG. 24 VARIATION OF MECHANICAL PROPERTIES OF STEEL WITH TEMPERATURE

For temperature less than 215 °C no reduction in the yield stress need to be considered.

22.4.2 Variation of Modulus of Elasticity and Shear Modulus with Temperature

The influence of temperature on the modulus of elasticity shall be taken as follows for structures of mild steels and high strength low alloy steels:

$$\frac{E(T)}{E(20)} \text{ and } \frac{G(T)}{G(20)} = 1.0 + \left[\frac{T}{2000 \left[\ln \left(\frac{T}{100} \right) \right]} \right] \text{ when } 0^\circ\text{C} < T \leq 600^\circ\text{C}$$

$$= \frac{690 \left(1 - \frac{T}{1000} \right)}{T - 53.5} \quad \text{when } 600^\circ\text{C} < T \leq 1000^\circ\text{C}$$

where

$E(T)$ = Modulus of elasticity of steel at $T^\circ\text{C}$, and
 $E(20)$ = Modulus of elasticity of steel at 20°C (room temperature).
 $G(T)$ = Shear Modulus of steel at $T^\circ\text{C}$, and

$G(20)$ = Shear Modulus of steel at 20 °C (room temperature).

This relationship is shown by curve 2 in Fig. 24.

22.4.3 For special steel with higher temperature resistance, such as TMCP steels, the manufacturer's recommendation shall be used to obtain the variation of yield strength and modulus of elasticity of steel with temperature.

22.5 Limiting Steel Temperature

The limiting steel temperature (T_l), in °C, in the case of structural steels, shall be calculated by substituting f_y , f_u , E , and G values with $f_y(T)$, $f_u(T)$, $E(T)$, and $G(T)$ calculated in accordance with **22.4**, respectively in **13**, **14**, **15**, and **16** to calculate the design capacity of the member as a function of steel temperature. The limiting temperature (T_l) will be the temperature at which the design capacity is equal to the design action on the member.

The design action under fire shall consider the following:

- a) Loads as per the load combinations for fire conditions given in Table 4.
- b) Effects of restraint to expansion of the elements during fire.
- c) Reduced bond likely under fire.

Limiting steel temperature for special steels may be appropriately calculated using the thermal characteristics of the material obtained from the supplier of the steel.

22.6 Temperature Increase with Time in Protected Members

22.6.1 The time (t) at which the limiting temperature (T_l) is attained shall be determined by calculation on the basis of a suitable series of fire tests in accordance with **22.6.2** or from the results of a single test in accordance with **22.6.3**.

22.6.1.1 For beams and for all members with a four-sided fire exposure condition, the limiting temperature (T_l) shall be taken as the average of all of the temperatures measured at the thermocouple locations on all sides.

22.6.1.2 For columns with a three-sided fire exposure condition, the limiting temperature (T_l) shall be taken as the average of the temperatures measured at the thermocouple locations on the face farthest from the wall. Alternatively, the temperatures from members with a four-sided fire exposure condition and having the same surface area to mass ratio may be used.

22.6.2 Temperature Based on Test Series

Calculation of the variation of steel temperature with time shall be by interpolation of the results of a series of fire tests using the regression analysis equation specified in **22.6.2.1**, subject to the limitations and conditions of **22.6.2.3**.

22.6.2.1 Regression analysis

The relationship between temperature (T) and time (t) for a series of tests on a group shall be calculated by least-square regression as follows:

$$t = k_0 + k_1 h_i + k_2 \left(\frac{h_i}{k_{sm}} \right) + k_3 T + k_4 h_i T + k_5 \left(\frac{h_i T}{k_{sm}} \right) + k_6 \left(\frac{T}{k_{sm}} \right)$$

where

- t = time from the start of the test, in min;
- k_0 to k_6 = regression coefficients from test data (see **22.6.2.2**);
- h_i = thickness of fire protection material, in mm;
- T = steel temperature, in °C obtained from test as given in **22.6.1**, $T > 250$ °C;
- and
- k_{sm} = exposed surface area to mass ratio, in $10^3 \text{ mm}^2/\text{kg}$.

22.6.2.2 *In lieu of* test results, the values for coefficients in Table 30 may be used in the equation **22.6.2.1** when the test satisfies the conditions specified in **22.6.2.3**.

Table 30 Regression Coefficients, k
(Clause 22.6.2.2)

k_0	k_1	k_2	k_3	k_4	k_5	k_6
(1)	(2)	(3)	(4)	(5)	(6)	(7)
- 25.90	1.698	- 13.71	0.030 0	0.000 5	0.514 4	6.633

22.6.2.3 Limitations and conditions on use of regression analysis

Test data to be utilized in accordance with **22.6.2.1**, shall satisfy the following:

- a) Steel members shall be protected with board, sprayed blanket or similar insulation materials having a dry density less than $1\,000 \text{ kg/m}^3$;
- b) All tests shall incorporate the same fire protection system;
- c) All members shall have the same fire exposure condition;
- d) Test series shall include at least nine tests;
- e) Test series may include prototypes which have not been loaded provided that stickability has been demonstrated; and
- f) All members subject to a three-sided fire exposure condition shall be within a group in accordance with **22.9**.

The regression equation obtained for one fire protection system may be applied to another system using the same fire protection material and the same fire exposure condition provided that stickability has been demonstrated for the second system.

A regression equation obtained using prototypes with a four-sided fire exposure condition may be applied to a member with a three-sided fire exposure condition provided that stickability has been demonstrated for the three-sided case.

22.6.3 Temperature Based on Single Test

The variation of steel temperature with time measured in a standard fire test may be used without modification provided:

- a) Fire protection system is the same as the prototype;
- b) Fire exposure condition is the same as the prototype;
- c) Fire protection material thickness is equal to or greater than that of the prototype;
- d) Surface area to mass ratio is equal to or less than that of the prototype; and
- e) Where the prototype has been submitted to a standard fire test in an unloaded condition, stickability has been separately demonstrated.

22.6.4 Parameters of Importance in the Standard Fire Test

- a) Specimen type, loading, configuration,
- b) Exposed surface area to mass ratio,
- c) Insulation type, thermal properties and thickness, and
- d) Moisture content of the insulation material.

22.7 Temperature Increase with Time in Unprotected Members

The time (t) at which the limiting temperature (T_l) is attained shall be calculated using the following equations:

- a) Three-sided fire exposure condition

$$t = -5.2 + 0.022 \ 1 \ T + \left(\frac{0.433 T_l}{k_{sm}} \right)$$

- b) Four-sided fire exposure condition

$$t = -4.7 + 0.026 \ 3 \ T + \left(\frac{0.213 T_l}{k_{sm}} \right)$$

where

t = time from the start of the test, in min;

T = steel temperature, in °C, $500 \text{ °C} \leq T \leq 750 \text{ °C}$, and

k_{sm} = exposed surface area to mass ratio, $2 \times 10^3 \text{ mm}^2/\text{kg} \leq k_{sm} \leq 35 \times 10^3 \text{ mm}^2/\text{kg}$.

For temperatures below 500 °C, linear interpolation shall be used, based on the time at 500 °C and an initial temperature of 20 °C at t equals 0.

22.8 Determination of PSA from a Single Test

The period of structural adequacy (PSA) determined from a single test may be applied without modification provided:

- Conditions, specified in **22.6.3** are satisfied,
- Conditions of support are the same as the prototype and the restraints are not less favourable than those of the prototype, and
- Ratio of the design load for fire to the design capacity of the member is less than or equal to that of the prototype.

(a) EFFECTIVE THICKNESS

(b) BLOCKING OF RIB VOIDS

FIG. 25 THREE SIDED FIRE EXPOSURE CONDITION REQUIREMENTS

22.9 Three-sided Fire Exposure Condition

Members subject to a three-sided fire exposure condition shall be considered in separate groups unless the following conditions are satisfied:

- The characteristics of the members of a group as given below, shall not vary from one another by more than:

- 1) Concrete density: $\left(\frac{\text{highest in group}}{\text{lowest in group}} \right) \leq 1.25$, and
- 2) Effective thickness (h_e): $\left(\frac{\text{largest in group}}{\text{smallest in group}} \right) \leq 1.25$

where the effective thickness (h_e) is equal to the cross sectional area excluding voids per unit width, as shown in Fig. 25 (a).

b) Rib voids shall either be:

- 1) all open; or
- 2) all blocked as shown in Fig. 25 (b).

c) Concrete slabs may incorporate permanent steel deck formwork.

22.10 Special Considerations

22.10.1 Connections

Connections shall be protected with the maximum thickness of fire protection material required for any of the members framing into the connection to achieve their respective fire-resistance levels. This thickness shall be maintained over all connection components, including bolt heads, welds and splice plates.

22.10.2 Web Penetrations

The thickness of fire protection material at and adjacent to web penetrations shall be the greatest of that required, when:

- a) area above the penetration is considered as a three-sided fire exposure condition (k_{sm1}) (see Fig. 26),
- b) area below the penetration is considered as a four-sided fire exposure condition (k_{sm2}) (see Fig. 26), and
- c) section as a whole is considered as a three-sided fire exposure condition (k_{sm}) (see Fig. 26).

This thickness shall be applied over the full beam depth and shall extend on each side of the penetration for a distance at least equal to the beam depth and not less than 300 mm.

22.11 Fire Resistance Rating

The fire resistance rating of various building components such as walls, columns, beams, and floors are given in Table 31 and Table 32. Fire damage assessment of various structural elements of the building and adequacy of the structural repairs can be done by

the fire resistance rating for encased steel column and beam (see Table 31 and Table 32).

FIG. 26 WEB PENETRATION

¹⁾ So fixed or designed, as to allow full penetration for mechanical bond.

- 2) Where wire binding cannot be used, expert advice should be sought regarding alternative methods of support to enable the lower edges of the plasterboard to be fixed together and to the lower flange, and for the top edge of the plasterboard to be held in position.
 - 3) Reinforcement shall consist of steel binding wire not less than 2.3 mm in diameter, or a steel mesh weighing not less than 0.5 kg/m². In concrete protection, the spacing of that reinforcement shall not exceed 200 mm in any direction.
 - 4) Concrete not assumed to be load bearing, reinforced.
-

23 SUSTAINABLE STEEL CONSTRUCTION

23.1 General

This Chapter specifies general requirements and practices for achieving environmentally sustainable steelwork building construction. This supplements the requirements of the other chapters of this specification.

23.2 Principles of Sustainable Steel Construction

- a) The structural steel design should provide a structure capable of fulfilling its intended function while sustaining the specified loads for its intended life with due regard to sustainability, robustness, economy, health and safety. Any expected change in the intended function during its life time should also be considered.
- b) In environmentally sustainable construction all stake holders should consider the broader and holistic implications of the decision, which include the whole life cycle sustainability, impacts on other parts of the building and the project, externalities, maintenance, societal cost and consequences, without impinging upon safety and efficiency of the structure.
- c) All parties in the supply chain for structural steelwork should take practical steps to reduce the greenhouse gas emissions of the processes over which they have control, thus contributing to sustainable construction. Further, construction operations should avoid/minimize polluting the environment with dust, wastewater, chemicals and leaching debris.
- d) Steelmaking should fully use of available secondary material (scrap) globally.
- e) Structural steelwork should be designed, detailed, and constructed to minimize material use and wastage of material and facilitate its recovery for reuse at its end-of-life, as a part of the circular economy, to the extent that this is reasonably practicable.
- f) The design should consider practical aspects of construction to avoid repair and rework.

23.3 Specification Requirements from Supply Chain Members

23.3.1 Requirements from Employer

- a) Appointment of key contractors (Architects, contractors for Steel work, cladding, glazing, Mechanical, Electrical, coating systems, etc.) as early as practical to ensure decisions are fully coordinated.
- b) Maximization of structural zones that facilitate lean and efficient designs
- c) Flexibility in design, if use of reclaim materials is considered.

23.3.2 Requirements from Main Contractor

- a) Early engagement of supply chain and subcontractors with emphasis on sustainability
- b) Judicious site planning to receive material, use of labour and location of machinery for efficient handling and construction.

23.3.3 Requirements from the Engineering Group

- a) Design for material efficiency, equipment efficiency, and minimal embodied energy and longevity.
- b) Consider holistically the environmental impact implication of temporary works and supports.
- c) Design with inbuilt flexibility and adaptability.
- d) Consider the economic and environmental implications of the type of connections chosen.
- e) Assess the requirement of protective treatment against corrosion and fire to minimize the life time maintenance and avoid over-specification.

23.3.4 Requirements from Steelwork Contractor

Establish a carbon reduction plan in steelwork. This may include use of low carbon emission transport, maximize the steelwork loads, optimizing haulage routes, minimizing empty runs, etc.

23.4 Sustainable Design

23.4.1 General

The environmental impacts associated with steelwork building construction be greatly reduced during the design process by:

- a) reducing the material in the structure
- b) minimizing fabrication, and avoidance of maintenance during service life.
- c) Identifying environmental improvements at the conceptual design stage requires the involvement of all the stakeholders such as architects, steelwork contractor during all design stages. Collaborative design processes result in
 - 1) materials being used more efficiently,
 - 2) fewer on-site changes and
 - 3) reduced environmental impacts.

Greenhouse gas or carbon emissions currently being the priority, action is required by all parts of the supply chain for the sector to decarbonize in line with global targets. This includes supply-side measures, in particularly decarbonizing steel-making and also demand-side measures including more efficient design and design for longevity, deconstruction and reuse.

Greenhouse gas emission should be based on life cycle assessment, which should include emissions in material manufacturing, transport, fabrication, erection, finishing, commissioning, maintenance during life and finally at the end of useful life deconstruction and disposal of the materials as waste or through recycling and reuse.

Further, environmentally friendly designs should be implemented in the construction projects and pollution of the environment during the process of construction should be avoided, if not minimized.

23.4.2 *Minimizing Material Consumption through Design*

Minimizing material consumption through design may be achieved by:

- a) Avoiding over-specification of design loads;
- b) Optimizing spans and grids: and adapting the building layout to take full advantage of the structural steelwork's attributes;
- c) Minimizing complex load paths and transfers in order to maximize direct load paths to ground;
- d) Ensuring that structural deflection and vibration criteria, coordination zones and member depths are appropriate and allow for efficient structural solutions that avoid excessive material use;
- e) Aiming to design for utilizations as close to 1.0 as practically possible, with due regard to permanent and temporary conditions;
- f) Specifying higher strength steel grades in members or part of members not governed by serviceability criteria;
- g) Considering key load paths, anticipated connection types and accurate loading criteria, in order to facilitate lean design principles;
- h) Avoiding the over rationalization of steel member sizes to ensure efficient use of material, with due consideration of minimum economic quantities for procurement;
- j) Reviewing section sizes and minimizing weight, whilst complying with safe methods of erection and fire protection requirements;
- k) Semi-continuous design, which assumes that the joints transfer moments from the beam to the column and allow rotation between the connected members as the load is resisted;

Note – Historically, steelwork design and fabrication has mainly been driven by cost however, sustainability and particularly the climate emergency, are likely to change this with more clients willing or mandated to pay more for sustainable and low carbon buildings. Reducing the carbon

impact of steel structures through lean and less conservative design is technically achievable but can require more design effort and more complex fabrication.

23.4.3 Design for Adaptability and Deconstruction

Design engineer should review design options with the steelwork contractor that may contribute to future flexibility, adaptability, deconstruction and reuse of the building structure, such as:

- a) How the building design and information records about the materials and members can facilitate future, remodelling, deconstruction and recovery for reuse and recycling;
- b) Ensuring accessibility to members and connections to allow for deconstruction and for ease of strengthening in the future;
- c) Greater standardization of sections sizes, lengths and connections, if appropriate from adaptability and deconstruction

23.5 Sustainable Fabrication

23.5.1 Information Records

A non-exhaustive checklist of information to be communicated in sustainable fabrication are given below:

a) Sustainability information to be provided to the steelwork contractor:

- 1) Any part of the steelwork that is to incorporate reclaimed steel products,
- 2) Any part of the steelwork that is to be left untreated,
- 3) Any details of the fire design, namely the design utilization per section size in the fire condition;
- 4) Any workshop waste targets;
- 5) A life cycle assessment of the whole building,
- 6) Any specific material sourcing requirements,

b) Sustainability information to be provided by the Steelwork Contractor:

- 1) All relevant EPDs for the steel and other products,
- 2) The embodied carbon of the fabricated steelwork;
- 3) Digital records of the 'As erected' structure, which should include all environmental,
- 4) Material quality and quantity data, including batch traceability for main structural,
- 5) Members, to facilitate future reuse (to be included in the operation and maintenance,
- 6) Manual,
- 7) Evidence of having in place an environmental management system

23.5.2 Fabrication Waste Management

Strategies for fabrication waste management include:

- a) Ordering directly from mills to minimize offcuts.
- b) Using stock lengths as ordered efficiently to minimize waste. Where possible, splice locations in steel members should be coordinated to fall within standard stock length sizes.
- c) Recycling and reusing steel fabrication waste, for example, off-cuts, swarf, etc.
- d) considering use off-cuts of material, particularly from plate, elsewhere, for example, temporary works, connection fittings, shims, packs, rather than simply scrapping for recycling. Always prioritized reuse over recycling.
- e) Considering use of machines that facilitate common line cutting of fittings.
- f) minimizing coating waste and coating packaging waste, by using intermediate bulk
- g) Minimizing/ avoiding overspray of coatings should ensure operators are properly trained and the appropriate and properly maintained equipment is used.

23.5.3 Sustainable Welding

Strategies for sustainable welding include:

- a) Avoiding low productivity processes and using automatic and semi-automatic processes with continuous wire feed, thus using materially efficiently and avoiding energy waste;
- b) Adopting energy-saving processes such as, inverter-based power sources instead of older regulator/rectifier-based sources, electrically powered pre-heating with temperature control instead of gas flame;
- c) Minimizing pre-heat in the welding procedure specification and welding continuously to avoid the need to re-heat.
- d) Periodically reviewing welding techniques and weld procedures to make the best use of the latest advancements in welding equipment and consumables, including the selection of joint set-ups and consumables that allow for deeper penetration fillet welds to be achieved, thus potentially reducing the number of weld runs required.

23.5.4 Sustainable Fire and Corrosion Protection Systems

23.5.4.1 Untreated steelwork

Any part of the steelwork such as steelwork in a less corrosivity category, that is to be left untreated shall be identified in the Project Specification.

23.5.4.2 Paint systems

The protective coating system shall satisfy the requirements from Clauses

23.5.4.3 *Intumescent systems*

For the same fire resistance water-based acrylic intumescent likely to have a lower environmental impact, when compared to solvent-based acrylic intumescent,

23.5.4.4 *Hot-dip galvanizing*

Requirements for thicker coatings, for example, by prior grit blasting, should be avoided by prior assessment of the predicted galvanized coating life and the minimum thickness required to avoid over-specification. For certain steel members (for example, with higher reactivity during galvanizing and/or larger section thickness), thicker coatings may also be achieved without grit blasting. Design and fabrication considerations for hot dip galvanizing should ensure adequate drainage and optimize material efficiency. Plan should optimize transport distances and provide direct delivery to the construction works, where feasible.

24 FABRICATION AND ERECTION

24.1 General

Tolerances for fabrication of steel structures shall conform to the accepted standard [6-6A(42)]. Tolerances for erection of steel structures shall conform to the accepted standard [6-6A(43)]. For general guidance on fabrication by welding, reference may be made to good practice [6-6A(44)].

24.2 Fabrication Procedures

24.2.1 *Straightening*

Material shall be straightened or formed to the specified configuration by methods that will not reduce the properties of the material below the values used in design. Local application of pressure at room or at elevated temperature or other thermal means may be used for straightening, provided the above is satisfied.

24.2.2 *Clearances*

The erection clearance for cleated ends of members, connecting steel to steel should preferably be not greater than 2.0 mm at each end. The erection clearance at ends of beams without web cleats should be not more than 3 mm at each end. Where for practical reasons, greater clearance is necessary, suitably designed seating should be provided.

24.2.2.1 The holes for bolts may be made as given in Table 19 of **17.2.1**, unless otherwise specified by the engineer. The hole diameter in base plates shall not exceed the anchor bolt diameter by more than 6 mm.

24.2.2.2 In friction type of connection clearance may be maintained, unless specified otherwise in the design document.

24.2.3 *Cutting*

Cutting shall be effected by sawing, shearing, cropping, machining or thermal cutting process. Shearing, cropping and gas cutting shall be clean, reasonably square, and free from any distortion. Should the inspector find it necessary, the edges shall be ground after cutting. Planning or finishing of sheared or gas-cut edges of plates or shapes shall not be required, unless specially noted on drawing or included in stipulated edge preparation for welding or when specifically required in the following section.

Re-entrant corners shall be free from notches and shall have largest practical radii with a minimum radius of 15 mm.

24.2.3.1 *Shearing*

Shearing of items over 16 mm thick to be galvanized and subject to tensile force or bending moment shall not be carried out, unless the item is stress relieved subsequently.

The use of sheared edges in the tension area shall be avoided in location subject to plastic hinge rotation at factored loading.

24.2.3.2 *Thermal cutting*

Gas cutting of high tensile steel by mechanically controlled torch may be permitted, provided special care is taken to leave sufficient metal to be removed by machining, so that all metal that has been hardened by flame is removed. Hand flame cutting may be permitted only subject to the approval of the inspecting authority.

Except where the material is subsequently joined by welding, no load shall be transmitted through a gas cut surface.

Thermally cut free edges, which shall be subject to calculated static tensile stress shall be free from round bottom gouges greater than 5 mm deep. Gouges greater than 5 mm deep and notches shall be removed by grinding.

24.2.4 *Holing*

24.2.4.1 Holes through more than one thickness of material for members, such as compound stanchion and girder flanges, shall be where possible, drilled after the members are assembled and tightly clamped or bolted together. A round hole for a bolt

shall either be machine flame cut, or drilled full size, or sub-punched 3 mm undersize and reamed to size or punched full size.

Hand flame cutting of a bolt hole shall not be permitted except as a site rectification measure for holes in column base plates.

24.2.4.2 Punching

A punched hole shall be permitted only in material whose yield stress (f_y) does not exceed 360 MPa and where thickness does not exceed $(5600/f_y)$ mm. In cyclically loaded details, punching shall be avoided in plates with thickness greater than 12 mm.

For greater thickness and cyclically loaded details, holes shall be either drilled from the solid or sub-punched or sub drilled and reamed.

The die for all sub-punched holes or the drill for all sub-drilled holes shall be at least 3 mm smaller than the required diameter of finished hole.

24.2.4.3 Oversize holes

A special plate washer of minimum thickness 4 mm shall be used under the nut, if the hole diameter is larger than the bolt diameter by 3 mm or more.

Oversize hole shall not exceed $1.25d$ or $(d + 8)$ mm in diameter, where d is the nominal bolt diameter, in mm.

A short slotted hole shall not exceed the appropriate hole size in width and $1.33d$ in length. A long slotted hole shall not exceed the appropriate hole size in width and $2.5d$ in length. If the slot length is larger than those specified, shear transfer in the direction of slot is not admissible even in friction type of connection.

Slotted holes shall be punched either in one operation or else formed by punching or drilling two round holes apart and completed by high quality mechanically controlled flame cutting and dressing to ensure that bolt can freely travel the full length of the slot.

24.2.4.4 Fitted bolt holes

Holes for turned and fitted bolts shall be drilled to a diameter equal to the nominal diameter of the shank or barrel subject to tolerance specified in the accepted standards [6-6A(45)]. Preferably, parts to be connected with close tolerance or barrel bolts shall be firmly held together by tacking bolts or clamps and the holes drilled through all the thicknesses at one operation and subsequently reamed to size. All holes not drilled through all thicknesses at one operation shall be drilled to a smaller size and reamed out after assembly. Where this is not practicable, the parts shall be drilled and reamed separately through hard bushed steel jigs.

24.2.4.5 Holes for rivets or bolts shall not be formed generally by gas cutting process. However, advanced gas cutting processes such as plasma cutting may be used to make holes in statically loaded members only. In cyclically loaded members subjected to tensile stresses which are vulnerable under fatigue, gas cutting shall not be used unless subsequent reaming is done to remove the material in the heat affected zone around the hole.

24.3 Assembly

All parts of bolted members shall be pinned or bolted and rigidly held together during assembly.

The component parts shall be assembled and aligned in such a manner that they are neither twisted nor otherwise damaged, and shall be so prepared that the specified camber, if any, is provided.

24.3.1 Holes in Assembly

When holes are drilled in one operation through two or more separable parts, these parts, when so specified by the engineer, shall be separated after drilling and the burrs removed.

Matching holes for rivets and black bolts shall register with each other so that a gauge of 1.5 mm or 2.0 mm (as the case may be, depending on whether the diameter of the rivet or bolt is less than or more than 25 mm) less in diameter than the diameter of the hole will pass freely through the assembled members in the direction at right angle to such members.

Drilling done during assembly to align holes shall not distort the metal or enlarge the holes.

Holes in adjacent part shall match sufficiently well to permit easy entry of bolts. If necessary, holes except oversize or slotted holes may be enlarged to admit bolts, by moderate amount of reaming.

24.3.2 Thread Length

When design is based on bolts with unthreaded shanks in the shear plane, appropriate measures shall be specified to ensure that, after allowing for tolerance, neither the threads nor the thread run-out be in the shear plane.

The length of bolt shall be such that at least one clear thread shows above the nut and at least one thread plus the thread run out is clear beneath the nut after tightening. One washer shall be provided under the rotated part.

24.3.3 Assembly Subjected to Vibration

When non-preloaded bolts are used in a structure subject to vibration, the nuts shall be secured by locking devices or other mechanical means. The nuts of preloaded bolts may be assumed to be sufficiently secured by the normal tightening procedure.

24.3.4 Washers

Washers are not normally required on non-preloaded bolts, unless specified otherwise. Tapered washers shall be used where the surface is inclined at more than 3° to a plane perpendicular to the bolt axis.

Hardened washer shall be used for preloaded bolts or the nut, whichever is to be rotated.

All material within the grip of the bolt shall be steel and no compressible material shall be permitted in the grip.

24.4 Riveting

24.4.1 Rivets shall be heated uniformly throughout their length, without burning or excessive scaling, and shall be of sufficient length to provide a head of standard dimensions. These shall, when driven, completely fill the holes and, if countersunk, the countersinking shall be fully filled by the rivet. If required, any protrusion of the countersunk head shall be dressed off flush.

24.4.2 Riveted member shall have all parts firmly drawn and held together before and during riveting, and special care shall be taken in this respect for all single-riveted connections. For multiple riveted connections, a service bolt shall be provided in every third or fourth hole.

24.4.3 Wherever practicable, machine riveting shall be carried out by using machines of the steady pressure type.

24.4.4 All loose, burned or otherwise defective rivets shall be cut out and replaced before the structure is loaded, and special care shall be taken to inspect all single riveted connections.

24.4.5 Special care shall be taken in heating and driving long rivets.

24.5 Bolting

24.5.1 In all cases where the full bearing area of the bolt is to be developed, the bolt shall be provided with a washer of sufficient thickness under the nut to avoid any threaded portion of the bolt being within the thickness or the parts bolted together, unless accounted for in design.

24.5.2 Pre-tensioned bolts shall be subjected to initial tension (the proof stress) by an appropriate pre-calibrated method.

24.6 Welding

24.6.1 Welding shall be in accordance with good practices [6-6A(46)], as appropriate.

24.6.2 For welding of any particular type of joint, welders shall give evidence acceptable to the purchaser of having satisfactorily completed appropriate tests as prescribed in good practices [6-6A(47)], as relevant.

24.6.3 Assembly and welding shall be carried out in such a way to minimize distortion and residual stress and that the final dimensions are within appropriate tolerances.

24.7 Machining of Butts, Caps and Bases

24.7.1 Column splices and butt joints of struts and compression members, depending on contact for stress transmission, shall be accurately machined and close-butted over the whole section with a clearance not exceeding 0.2 mm locally, at any place. Sum of all such clearance shall not be more than 30 percent of the contact area for stress transmission. In column caps and bases, the ends of shafts together with the attached gussets, angles, channels, etc; after connecting together should be accurately machined so that clearance between the contact surfaces shall not exceed 2 mm locally, subject further to the condition that sum total of all such clearance shall not exceed 30 percent of the total contact area for stress transmission. Care should be taken that these gussets, connecting angles or channels are fixed with such accuracy that they are not reduced in thickness by machining by more than 2.0 mm.

24.7.2 Where sufficient gussets and rivets or welds are provided to transmit the entire loading (see provisions under **11**), the column ends need not be machined.

24.7.3 Slab Bases and Caps

Slab bases and slab caps, except when cut from material with true surfaces, shall be accurately machined over the bearing surfaces and shall be in effective contact with the end of the stanchion, the bearing face which is to be grouted to fit tightly at both top and bottom, unless welds are provided to transmit the entire column face.

24.7.4 To facilitate grouting, sufficient gap shall be left between the base plates and top of pedestal and holes shall be provided where necessary in stanchion bases for the escape of air.

24.8 Painting

24.8.1 Painting shall be done in accordance with the good practice good practices [6-6A(48)].

22.8.2 All surfaces, which are to be painted, oiled or otherwise treated, shall be dry and thoroughly cleaned to remove all loose scale and loose rust.

24.8.3 Shop contact surfaces need not be painted unless specified. If so specified, they shall be brought together while the paint is still wet.

24.8.4 Surfaces not in contact, but inaccessible after shop assembly, shall receive the full specified protective treatment before assembly. This does not apply to the interior of sealed hollow sections.

24.8.5 Chequered plates shall be painted but the details of painting shall be specified by the purchaser.

24.8.6 In case of surfaces to be welded, the steel shall not be painted or metal coated within a suitable distance of any edge to be welded, if the paint specified or the metal coating is likely to be harmful to welders or impair the quality of the welds.

24.8.7 Welds and adjacent parent metal shall not be painted prior to de-slagging, inspection and approval.

24.8.8 Parts to be encased in concrete shall not be painted or oiled.

24.8.9 Contact surface in friction type connection shall not be painted in advance.

24.9 Marking

Each piece of steel work shall be distinctly marked before dispatch, in accordance with a marking diagram and shall bear such other marks as will facilitate erection.

24.10 Shop Erection

24.10.1 The steel work shall be temporarily shop erected complete or as arranged with the inspection agency so that accuracy of fit may be checked before dispatch. The parts shall be shop assembled with sufficient numbers of parallel drifts to bring and keep the parts in place.

24.10.2 In the case of parts drilled or punched, through steel jigs with bushes resulting in all similar parts being interchangeable, the steelwork may be shop erected in such position as arranged with the inspection agency.

24.10.3 In case of shop fabrication using numerically controlled machine data generated by computer software (like CAD), the shop erection may be dispensed with at the discretion of the inspector.

24.11 Packing

All projecting plates or bars and all ends of members at joints shall be stiffened, all straight bars and plates shall be bundled, all screwed ends and machined surfaces shall be

suitably packed and all rivets, bolts, nuts, washers and small and loose parts shall be packed separately in cases, so as to prevent damage or distortion during transit.

24.12 Inspection and Testing

24.12.1 The inspecting authority shall have free access at all reasonable times to those parts of the manufacturer's works which are concerned with the fabrication of the steelwork and shall be afforded all reasonable facilities for satisfying himself that the fabrication is being undertaken in accordance with the provisions of this section.

24.12.2 Unless specified otherwise, inspection shall be made at the place of manufacture prior to dispatch and shall be conducted so as not to interfere unnecessarily with the operation of the work.

24.12.3 The manufacturer shall guarantee compliance with the provisions of this standard, if required to do so by the purchaser.

24.12.4 Should any structure or part of a structure be found not to comply with any of the provisions of this section, it shall be liable to rejection. No structure or part of the structure, once rejected shall be resubmitted for test, except in cases where the purchaser or his authorized representative considers the defect as rectifiable.

24.12.5 Defects, which may appear during fabrication, shall be made good with the consent of and according to the procedure laid down by the inspecting authority.

24.12.6 All gauges and templates necessary to satisfy the inspection authority shall be supplied by the manufacturer. The inspecting authority may, at his discretion, check the test results obtained at the manufacturer's works by independent testing at outside laboratory, and should the material so tested be found to be unsatisfactory, the cost of such tests shall be borne by the manufacturer, and if found satisfactory, the cost shall be borne by the purchaser.

24.13 Site Erection

24.13.1 *Plant and Equipment*

The suitability and capacity of all plant and equipment used for erection shall be to the satisfaction of the engineer.

24.13.2 *Storing and Handling*

All structural steel should be so stored and handled at the site that the members are not subjected to excessive stresses and damage by corrosion due to exposure to environment.

24.13.3 *Setting Out*

The positioning and leveling of all steelwork, the plumbing of stanchions and the placing of every part of the structure with accuracy shall be in accordance with the approved drawings and to the satisfaction of the engineer in accordance with the deviation permitted below.

24.13.3.1 Erection tolerances

Unloaded steel structure, as erected, shall satisfy the criteria specified in Table 33 within the specified tolerance limits.

Each criterion given in the table shall be considered as a separate requirement, to be satisfied independent of any other tolerance criteria. The erection tolerances specified in Table 33 apply to the following reference points:

- a) For a column, the actual centre point of the column at each floor level and at the base, excluding any base-plate or cap-plate. The level of the base plate on pedestal shall be so as to avoid contact with soil and corrosive environment; and
- b) For a beam, the actual centre point of the top surface at each end of the beam, excluding any end-plate.

Table 33 Normal Tolerances after Erection
(Clause 24.13.3.1)

SI No.	Criterion	Permitted Deviation
(1)	(2)	(3)
i)	Deviation of distance between adjacent columns	5 mm
ii)	Inclination of a column in a multi-storey building between adjacent floor levels	$0.002h_s$ where h_s is the storey height
iii)	Deviation of location of a column in a multi-storey building at any floor level from a vertical line through the intended location of the column base	$0.003 \sum h_b/n^{0.5}$ where $\sum h_b$ is the total height from the base to the floor level concerned and n is the number of storeys from the base to the floor level concerned
iv)	Inclination of a column in a single storey building (not supporting a crane gantry) other than a portal frame	$0.003 \sum h_c$ where h_c is the height of the column

- | | | |
|----|---|---|
| v) | Inclination of the column of a portal frame (not supporting a crane gantry) | Mean: $0.002h_c$
Individual: $0.010h_c$
where h_c is the height of the column |
|----|---|---|

The straightness tolerances specified in Table 34 have been assumed in the derivation of the design stress for the relevant type of member. Where the curvature exceeds these values, the effect of additional curvature on the design calculations shall be reviewed.

A tension member shall not deviate from its correct position relative to the members to which it is connected by more than 3 mm along any setting axis.

**Table 34 Straightness Tolerances incorporated
in Design Rules**
(Clause 24.13.3.1)

SI No.	Criterion	Permitted Deviation
(1)	(2)	(3)
i)	Straightness of a column (or other compression member) between points which will be laterally restrained on completion of erection	0.001L generally, and 0.002L for members with hollow cross sections; where, L is the length between points which will be laterally restrained
ii)	Straightness of a compression flange of a beam, relative to the weak axis, between points, which will be laterally restrained on completion of erection	0.001L generally, and 0.002L for members with hollow cross sections; where, L is the length between points which will be laterally restrained

24.13.4 Safety during Fabrication and Erection

24.13.4.1 All steel materials including fabricated structures, either at fabrication shop or at erection site, shall be handled only by a worker skilled in such jobs; where necessary with load tested lifting devices, having tested wire rope slings of correct size. The devices should be well maintained and operated by experienced operators.

24.13.4.2 Oxygen and acetylene cylinders and their hoses shall have distinctive colours. Cylinders should be stored in upright position in well-ventilated rooms or in open air, not exposed to flames, naked lights or extreme heat and should also be in upright position when they are being used. All gas cutting works shall be done only by experienced skilled gas cutters, equipped with gloves, boots, aprons, goggles and good cutting sets of approved make.

24.13.4.3 While doing any welding work, it should be ensured that the welding machine is earthed and the welding cables are free from damage. The welder and his assistant shall use a face shield or head shield with a welding lens and clear cover glass and their hands, legs and bodies shall be well protected by leather gloves, shoes and aprons. Combustible materials should be kept away from the sparks and globules of molten metals generated in any arc welding. In case of welding in a confined place, it should be provided with an exhaust system to take care of the harmful gases, fumes and dusts generated.

24.13.4.4 In addition to precautions against all the hazards mentioned above, erection workers shall also be protected in the following manner:

- a) All workers shall wear helmets and shall also be provided with gloves and shoes. In addition those working at heights shall use safety belts.
- b) All structures shall be so braced/guyed during erection that there is no possibility of collapse before erection work is completed.
- c) Warning signs such as 'Danger', 'Caution', '440 volts', 'Do not smoke', 'Look ahead', etc; should be displayed at appropriate places.

24.13.4.5 For detailed safety precautions during erection, reference shall be made to the good practice [6-6A(49)].

24.13.5 *Field Connections*

24.13.5.1 *Field riveting*

Rivets driven at the site shall be heated and driven with the same care as those driven in the shop.

24.13.5.2 *Field bolting*

Field bolting shall be carried out with the same care as required for shop bolting.

24.13.5.3 *Fillet welding*

Field assembly and welding shall be executed in accordance with the requirements for shop fabrications excepting such as manifestly apply to shop conditions only. Where the steel has been delivered painted, the paint shall be removed for a distance of at least 50 mm on either side of the joint.

24.14 *Painting after Erection*

23.14.1 Before painting of such steel which is delivered unpainted is commenced, all surfaces to be painted shall be dry and thoroughly cleaned from all loose scale and rust, as required by the surface protection specification.

24.14.2 The specified protective treatment shall be completed after erection. All rivet and bolt heads and the site welds after de-slagging shall be cleaned. Damaged or deteriorated paint surfaces shall first be made good with the same type of paint as the shop coat. Where specified, surfaces which will be in contact after site assembly, shall receive a coat of paint (in addition to any shop priming) and shall be brought together while the paint is still wet. No painting shall be used on contact surfaces in the friction connection, unless specified otherwise by the design document.

24.14.3 Where the steel has received a metal coating in the shop, this coating shall be completed on site so as to be continuous over any welds and site rivets or bolts, subject to the approval of the engineer. Painting on site may complete protection. Bolts, which have been galvanized or similarly treated, are exempted from this requirement.

24.14.4 Surface, which will be inaccessible after site assembly, shall receive the full-specified protective treatment before assembly.

24.14.5 Site painting should not be done in frosty or foggy weather, or when humidity is such as to cause condensation on the surfaces to be painted.

24.15 Bedding Requirement

23.15.1 Bedding shall be carried out with Portland cement grout or mortar, as described under **23.15.4** or fine cement concrete in accordance with good practice [6-6A(50)].

24.15.2 For multi-storeyed buildings, this operation shall not be carried out until a sufficient number of bottom lengths of stanchions have been properly lined, levelled and plumbed and sufficient floor beams are in position.

24.15.3 Whatever method is employed, the operation shall not be carried out until the steelwork has been finally levelled and plumbed, stanchion bases being supported meanwhile by steel wedges or nuts; and immediately before grouting, the space under the steel shall be thoroughly cleaned.

24.15.4 Bedding of structure shall be carried out with grout or mortar, which shall be of adequate strength and shall completely fill the space to be grouted and shall either be placed under pressure or by ramming against fixed supports. The grouts or mortar used shall be non-shrinking variety.

24.16 Steelwork Tenders and Contracts

A few recommendations are given in Annex J for general information.

ANNEX A
[Clause 4]

Symbols used in this section shall have the following meanings with respect to the structure or member or condition, unless otherwise defined elsewhere in this Section:

A	—	Area of cross section
A_c	—	Area at root of threads
A_e	—	Effective cross sectional area
A_{ef}	—	Reduced effective flange area
A_f	—	Total flange area
A_g	—	Gross cross sectional area
A_{gf}	—	Gross cross sectional area of flange
A_{go}	—	Gross cross sectional area of outstanding (not connected) leg of a member
A_n	—	Net area of the total cross section
A_{nb}	—	Net tensile cross sectional area of bolt
A_{nc}	—	Net cross sectional area of the connected leg of a member
A_{nf}	—	Net cross sectional area of each flange
A_{no}	—	Net cross sectional area of outstanding (not connected) leg of a member
A_{pb}	—	Nominal bearing area of bolt on any plate
A_q	—	Cross sectional area of a bearing (load carrying) stiffener in contact with the flange
A_s	—	Tensile stress area
A_{sb}	—	Gross cross sectional area of a bolt at the shank
A_{tg}	—	Gross sectional area in tension from the centre of the hole to the toe of the angle section / channel section, etc (Block shear failure, see 13.4) perpendicular to the line of force
A_{tn}	—	Net sectional area in tension from the centre of the hole to the toe of the angle perpendicular to the line of force Block shear failure (see 13.4)
A_v	—	Shear area
A_{vg}	—	Gross cross sectional area in shear along the line of transmitted force (see 13.4)
A_{vn}	—	Net cross sectional area in shear along the line of transmitted force (see 13.4)
a, b	—	Larger and smaller projection of the slab base beyond the rectangle circumscribing the column, respectively (see 14.4)
a_o	—	Peak acceleration
a_1	—	Unsupported length of individual elements being laced between lacing points
B	—	Length of side of cap or base plate of a column
b	—	Outstand/width of the element
b_1	—	Stiff bearing length
b_e	—	Effective width of flange between pair of bolts
b_f	—	Width of the flange
b_i	—	Width of flange as an internal element

b_o	—	Width of flange outstand
b_p	—	Panel zone width between column flanges at beam-column junction
b_s	—	Shear lag distance
b_t	—	Width of tension field
b_w	—	Width of outstanding leg
C	—	Centre to centre longitudinal distance of battens
C_m	—	Coefficient of thermal expansion
c	—	Spacing of transverse stiffener
c_b	—	Moment amplification factor for braced member
c_m	—	Moment reduction factor for lateral torsional buckling strength calculation
c_s	—	Moment amplification factor for sway frame
D	—	Overall depth/diameter of the cross section
d	—	Depth of web, Nominal diameter
d_2	—	Twice the clear distance from the compression flange angles, plates or tongue plates to the neutral axis
d_h	—	Diameter of a bolt/ rivet hole
d_o	—	Nominal diameter of the pipe column or the dimensions of the column in the depth direction of the base plate
d_p	—	Panel zone depth in the beam-column junction
E	—	Modulus of elasticity for steel
$E(T)$	—	Modulus of elasticity of steel at $T^\circ\text{C}$
$E(20)$	—	Modulus of elasticity of steel at 20°C
E_p	—	Modulus of elasticity of the panel material
F_{cdw}	—	Buckling strength of un-stiffened beam web under concentrated load
F_d	—	Factored design load
F_n	—	Normal force
F_o	—	Minimum proof pretension in high strength friction grip bolts
F_{psd}	—	Bearing capacity of load carrying stiffener
F_q	—	Stiffener force
F_{qd}	—	Stiffener buckling resistance
F_{test}	—	Test load
$F_{test,a}$	—	Load for acceptance test
$F_{test, Min}$	—	Minimum test load from the test to failure
$F_{test, R}$	—	Test load resistance
$F_{test, S}$	—	Strength test load
F_w	—	Design capacity of the web in bearing
F_x	—	External load, force or reaction
F_{xd}	—	Buckling resistance of load carrying web stiffener
f	—	Actual normal stress range for the detail category
f_1	—	Frequency for a simply supported one way system
f_2	—	Frequency of floor supported on steel girder perpendicular to the joist
f_a	—	Calculated stress due to axial force at service load
f_{abc}	—	Permissible bending stress in compression at service load
f_{ac}	—	Permissible compressive stress at service load
f_{abt}	—	Permissible bending stress in tension at service load
f_{apb}	—	Permissible bearing stress of the bolt at service load

f_{asb}	—	Permissible stress of the bolt in shear at service load
f_{at}	—	Permissible tensile stress at service load
f_{atb}	—	Permissible tensile stress of the bolt at service load
f_{aw}	—	Permissible stress of the weld at service load
f_b	—	Actual bending stress at service load
f_{bc}	—	Actual bending stress in compression at service load
f_{bd}	—	Design bending compressive stress corresponding to lateral buckling
f_{br}	—	Actual bearing stress due to bending at service load
f_{bt}	—	Actual bending stress in tension at service load
f_{bs}	—	Permissible bending stress in column base at service load
f_c	—	Actual axial compressive stress at service load
f_{cc}	—	Elastic buckling stress of a column, Euler buckling stress
f_{cd}	—	Design compressive stress
$f_{cr,b}$	—	Extreme fibre compressive stress corresponding to elastic lateral buckling moment
f_e	—	Equivalent stress at service load
f_f	—	Fatigue stress range corresponding to 5×10^6 cycles of loading
f_{feq}	—	Equivalent constant amplitude stress
f_{fd}	—	Design normal fatigue strength
$f_{f, Max}$	—	Highest normal stress range
f_{fn}	—	Normal fatigue stress range
f_{fnw}	—	Normal stress in weld at service load
f_o	—	Proof stress
f_p	—	Actual bearing stress at service load
f_{pb}	—	Actual bearing stress in bending at service load
f_{psd}	—	Bearing strength of the stiffeners
f_r	—	Frequency
f_{sb}	—	Actual shear stress in bolt at service load
f_t	—	Actual tensile stress at service load
f_{tb}	—	Actual tensile stress of the bolt at service load
f_u	—	Characteristic ultimate tensile stress
f_{ub}	—	Characteristic ultimate tensile stress of the bolt
f_{um}	—	Average ultimate stress of the material as obtained from test
f_{up}	—	Characteristic ultimate tensile stress of the connected plate
f_v	—	Applied shear stress in the panel designed utilizing tension field action
f_w	—	Actual stress of weld at service load
f_{wd}	—	Design stress of weld at service load
f_{wn}	—	Nominal strength of fillet weld
f_x	—	Maximum longitudinal stress under combined axial force and bending
f_y	—	Characteristic yield stress
$f_y(T)$	—	Yield stress of steel at $T^\circ\text{C}$
$f_y(20)$	—	Yield stress of steel at 20°C
f_{yb}	—	Characteristic yield stress of bolt
f_{yf}	—	Characteristic yield stress of flange
f_{ym}	—	Average yield stress as obtained from test
f_{yp}	—	Characteristic yield stress of connected plate

f_{yq}	—	Characteristic yield stress of stiffener material
f_{yw}	—	Characteristic yield stress of the web material
G	—	Modulus of rigidity for steel
G	—	Gauge length between centres of the holes perpendicular to the load direction, acceleration due to gravity
h	—	Depth of the section
h_b	—	Total height from the base to the floor level concerned
h_c	—	Height of the column
h_e	—	Effective thickness
h_f	—	Centre to centre distance of flanges
h_i	—	Thickness of fire protection material
h_L	—	Height of the lip
h_s	—	Storey height
h_y	—	Distance between shear centre of the two flanges of a cross section
I	—	Moment of inertia of the member about an axis perpendicular to the plane of the frame
I_{fc}	—	Moment of inertia of the compression flange of the beam about the axis parallel to the web
I_{ft}	—	Moment of inertia of the tension flange of the beam about minor axis
I_q	—	Moment of inertia of a pair of stiffener about the centre of the web, or a single stiffener about the face of the web.
I_s	—	Second moment of inertia
I_{so}	—	Second moment of inertia of the stiffener about the face of the element perpendicular to the web
I_T	—	Transformed moment of inertia of the one way system (in terms of equivalent steel, assuming the concrete flange of width equal to the spacing of the beam to be effective)
I_t	—	St. Venant's torsion constant
I_w	—	Warping constant
I_y	—	Moment of inertia about the minor axis of the cross section
I_z	—	Moment of inertia about the major axis of the cross section
K_b	—	Effective stiffness of the beam and column
K_h	—	Reduction factor to account for the high strength friction grip connection bolts in oversized and slotted holes
KL	—	Effective length of the member
KL/r	—	Appropriate effective slenderness ratio of the section
KL/r_y	—	Effective slenderness ratio of the section about the minor axis of the section
KL/r_z	—	Effective slenderness ratio of the section about the major axis of the section
$\left(\frac{KL}{r}\right)_o$	—	Actual maximum effective slenderness ratio of the laced column
$\left(\frac{KL}{r}\right)_e$	—	Effective slenderness ratio of the laced column accounting for shear deformation
K_v	—	Shear buckling co-efficient

K_w	—	Warping restraint factor
k	—	Regression coefficient
k_{sm}	—	Exposed surface area to mass ratio
K_y, K_z, K_{LT}	—	Moment amplification factors (see 11.4.2, 11.4.3.1, 11.4.3.3 and 16.3.2.2)
L	—	Actual length, unsupported length, length centre to centre distance of the intersecting members, cantilever length
L_c	—	Length of end connection in bolted and welded members, taken as the distance between outermost fasteners in the end connection, or the length of the end weld, measured along the length of the member
L_{LT}	—	Effective length for lateral torsional buckling
L_m	—	Maximum distance from the restraint to the compression flange at the plastic hinge to an adjacent restraint (limiting distance)
L_o	—	Length between points of zero moment (inflection) in the span
l	—	Centre to centre length of the supporting member
l_e	—	Distance between prying force and bolt centre line
l_g	—	Grip length of bolts in a connection
l_j	—	Length of the joint
l_s	—	Length between points of lateral support to the compression flange in a beam
l_v	—	Distance from bolt centre line to the toe of fillet weld or to half the root radius for a rolled section
l_w	—	Length of weld
M	—	Bending moment
M_a	—	Applied bending moment
M_{cr}	—	Elastic critical moment corresponding to lateral torsional buckling of the beam
M_d	—	Design flexural strength
M_{dv}	—	Moment capacity of the section under high shear
M_{dy}	—	Design bending strength about the minor axis of the cross section
M_{dz}	—	Design bending strength about the major axis of the cross section
M_{eff}	—	Reduced effective moment
M_{fr}	—	Reduced plastic moment capacity of the flange plate
M_{fd}	—	Design plastic resistance of the flange alone
M_{nd}	—	Design bending strength under combined axial force and uniaxial moment
M_{ndy}, M_{ndz}	—	Design bending strength under combined axial force and the respective uniaxial moment acting alone
M_p	—	Plastic moment capacity of the section
M_{pb}	—	Moment in the beam at the intersection of the beam and column centre lines
M_{pc}	—	Moments in the column above and below the beam surfaces
M_{pd}	—	Plastic design strength
M_{pdf}	—	Plastic design strength of flanges only
M_q	—	Applied moment on the stiffener
M_s	—	Moment at service (working) load
M_{tf}	—	Moment resistance of tension flange
M_y	—	Factored applied moment about the minor axis of the cross section

M_{yq}	—	Moment capacity of the stiffener based on its elastic modulus
M_z	—	Factored applied moment about the major axis of the cross section
N	—	Number of parallel planes of battens
N_d	—	Design strength in tension or in compression
N_f	—	Axial force in the flange
N_{SC}	—	Number of stress cycles
n	—	Number of bolts in the bolt group/critical section
n_e	—	Number of effective interfaces offering frictional resistance to slip
n_n	—	Number of shear planes with the threads intercepting the shear plane in the bolted connection
n_s	—	Number of shear planes without threads intercepting the shear plane in the bolted connection
P	—	Factored applied axial force
P_{cc}	—	Elastic buckling load
P_d	—	Design axial compressive strength
P_{dy}, P_{dz}	—	Design compression strength as governed by flexural buckling about the respective axis
P_e	—	Elastic Euler buckling load
P_{min}	—	Minimum required strength for each flange splice
P_r	—	Required compressive strength
P_s	—	Actual compression at service load
P_y	—	Yield strength of the cross section under axial compression
p	—	Pitch length between centers of holes parallel to the direction of the load
p_s	—	Staggered pitch length along the direction of the load between lines of the bolt holes (see Fig. 5)
Q	—	Prying force
Q_a	—	Accidental load (Action)
Q_c	—	Characteristic loads (Action)
Q_d	—	Design load (Action)
Q_p	—	Permanent loads (Action)
Q_v	—	Variable loads (Action)
q	—	Shear stress at service load
R	—	Ratio of the mean compressive stress in the web (equal to stress at mid depth) to yield stress of the web; reaction of the beam at support
R_d	—	Design strength of the member at room temperature
R_i	—	Net shear in bolt group at bolt 'i'
R_r	—	Response reduction factor
R_{tf}	—	Flange shear resistance
R_u	—	Ultimate strength of the member at room temperature
r	—	Appropriate radius of gyration
r_1	—	Minimum radius of gyration of the individual element being laced together
r_f	—	Ratio of the design action on the member under fire to the design capacity
r_{vv}	—	Radius of gyration about the minor axis (v-v) of angle section.

r_y	—	Radius of gyration about the minor axis
r_z	—	Radius of gyration about the major axis
S	—	Minimum transverse distance between the centroid of the rivet or bolt group or weld group
S_c	—	Constant stress range
S_d	—	Design strength
S_o	—	Original cross sectional area of the test specimen
S_p	—	Spring stiffness
S_u	—	Ultimate strength
s_c	—	Anchorage length of tension field along the compression flange
s_t	—	Anchorage length of tension field along the tension flange
s_a	—	Actual stiffener spacing
T	—	Temperature in degree Celsius; Factored tension
T_b	—	Applied tension in bolt
T_{cf}	—	Thickness of compression flange
T_d	—	Design strength under axial tension
T_{dg}	—	Yielding strength of gross section under axial tension
T_{dn}	—	Rupture strength of net section under axial tension
T_{db}	—	Design strength of bolt under axial tension, Block shear strength at end connection
T_e	—	Externally applied tension
T_f	—	Factored tension force of friction type bolt
T_l	—	Limiting temperature of the steel
T_{nb}	—	Nominal strength of bolt under axial tension
T_{nd}	—	Design tension capacity
T_{ndf}	—	Design tension capacity of friction type bolt
T_{nf}	—	Nominal tensile strength of friction type bolt
T_s	—	Actual tension under service load
t	—	Thickness of element/angle, time in minutes
t_f	—	Thickness of flange
t_p	—	Thickness of plate
t_{pk}	—	Thickness of packing
t_q	—	Thickness of stiffener
t_s	—	Thickness of base slab
t_t	—	Effective throat thickness of welds
t_w	—	Thickness of web,
V	—	Factored applied shear force
V_b	—	Shear in batten plate
V_{bf}	—	Factored frictional shear force in friction type connection
V_{cr}	—	Critical shear strength corresponding to web buckling
V_d	—	Design shear strength
V_{db}	—	Block shear strength
V_{nb}	—	Nominal shear strength of bolt
V_{nbf}	—	Bearing capacity of bolt for friction type connection
V_p	—	Plastic shear resistance under pure shear
V_n	—	Nominal shear strength

V_{npb}	—	Nominal bearing strength of bolt
V_{nsb}	—	Nominal shear capacity of a bolt
V_{nsf}	—	Nominal shear capacity of bolt as governed by slip in friction type connection
V_s	—	Transverse shear at service load
V_{sb}	—	Factored shear force in the bolt
V_{sd}	—	Design shear capacity
V_{sdf}	—	Design shear strength in friction type bolt
V_{sf}	—	Factored design shear force of friction bolts
V_t	—	Applied transverse shear
V_{tf}	—	Shear resistance in tension field
W	—	Total load
w	—	Uniform pressure from below on the slab base due to axial compression under the factored load
w_{tf}	—	Width of tension field
x_t	—	Torsional index
Z_e	—	Elastic section modulus
Z_{ec}	—	Elastic section modulus of the member with respect to extreme compression fibre
Z_{et}	—	Elastic section modulus of the member with respect to extreme tension fibre
Z_p	—	Plastic section modulus
Z_v	—	Contribution to the plastic section modulus of the total shear area of the cross section
y_g	—	Distance between point of application of the load and shear centre of the cross section
y_s	—	Co-ordinate of the shear centre in respect to centroid
α	—	Imperfection factor for buckling strength in columns and beams
α_t	—	Coefficient of thermal expansion
β_M	—	Ratio of smaller to the larger bending moment at the ends of a beam column
β_{My}, β_{Mz}	—	Equivalent uniform moment factor for flexural buckling for y-y and axes, respectively
β_{MLT}	—	Equivalent uniform moment factor for lateral torsional buckling
χ	—	Strength reduction factor to account for buckling under compression
χ_m	—	Strength reduction factor, χ , at f_{ym}
χ_{LT}	—	Strength reduction factor to account for lateral torsional buckling of beams
δ	—	Storey deflection
δ_L	—	Horizontal deflection of the bottom of storey due to combined gravity and notional load
δ_p	—	Load amplification factor
δ_u	—	Horizontal deflection of the top of storey due to combined gravity and notional load

ϕ	—	Inclination of the tension field stress in web
γ	—	Unit weight of steel
γ_f	—	Partial safety factor for load
γ_m	—	Partial safety factor for material
γ_{m0}	—	Partial safety factor against yield stress and buckling
γ_{m1}	—	Partial safety factor against ultimate stress
γ_{mb}	—	Partial safety factor for bolted connection with bearing type bolts
γ_{mf}	—	Partial safety factor for bolted connection with high strength friction grip bolts
γ_{fft}	—	Partial safety factor for fatigue load
γ_{mft}	—	Partial safety factor for fatigue strength
γ_{mv}	—	Partial safety factor against shear failure
γ_{mw}	—	Partial safety factor for strength of weld
ϵ	—	Yield stress ratio, $(250 / f_y)^{1/2}$
λ	—	Non dimensional slenderness ratio $= \sqrt{f_y (KL/r)^2 / \pi^2 E} = \sqrt{f_y / f_{cc}} = \sqrt{P_y / P_{cc}}$
λ_{cr}	—	Elastic buckling load factor
λ_e	—	Equivalent slenderness ratio
λ_{LT}	—	Non-dimensional slenderness ratio in lateral bending
λ_{scr}	—	Elastic buckling load factor of each storey
μ	—	Poisson's ratio
μ_c	—	Correction factor
μ_f	—	Coefficient of friction (slip factor)
μ_r	—	Capacity reduction factor
θ	—	Ratio of the rotation at the hinge point to the relative elastic rotation of the far end of the beam segment containing plastic hinge
ρ	—	Unit mass of steel
τ	—	Actual shear stress range for the detail category
τ_b	—	Buckling shear stress
τ_{ab}	—	Permissible shear stress at the service load
$\tau_{cr,e}$	—	Elastic critical shear stress
τ_f	—	Fatigue shear stress range
$\tau_{f, Max}$	—	Highest shear stress range
τ_d	—	Design shear fatigue strength
τ_n	—	Fatigue shear stress range at N_{sc} cycle for the detail category
τ_v	—	Actual shear stress at service load
ψ	—	Ratio of the moments at the ends of the laterally unsupported length of a beam
Γ	—	Frame buckling load factor

NOTE — The subscripts y, z denote the y-y and z-z axes of the section, respectively. For symmetrical sections, y-y denotes the minor principal axis whilst z-z denotes the major principal axis (see 8).

ANNEX B
[Clause 11.1.1(c)]**ANALYSIS AND DESIGN METHODS****B-1 ADVANCED STRUCTURAL ANALYSIS AND DESIGN****B-1.1 Analysis**

For a frame, comprising members of compact section with full lateral restraint, an advanced structural analysis may be carried out, provided the analysis can be shown to accurately model the actual behaviour of that class of frames. The analysis shall take into account the relevant material properties, residual stresses, geometrical imperfections, reduction in stiffness due to axial compression, second-order effects, section strength and ductility, erection procedures and interaction with the foundations.

Advanced structural analysis for earthquake loads shall take into account provisions of **5** of Part 6 'Structural Design' Section 1 'Loads, Forces and Effects' of the Code.

B-1.2 Design

For the strength limit state, it shall be sufficient to satisfy the section capacity requirements given under **15** for the members subjected to bending, under **14** for axial members, under **16** for combined forces and under **17** for connections. Effect of moment magnification given in **16**, instability given in **14** and lateral buckling given in **15** need not be considered while designing the member, since advanced analysis methods directly consider these.

B-2 SECOND ORDER ELASTIC ANALYSIS AND DESIGN**B-2.1 Analysis**

In a second-order elastic analysis, the members shall be assumed to remain elastic, and changes in frame geometry under the design load and changes in the effective stiffness of the members due to axial forces shall be accounted for. In a frame where the elastic buckling load factor (λ_{cr}) of the frame as determined in accordance with **10.6** is greater than 5, the changes in the effective stiffness of the members due to axial forces may be neglected.

B-2.2 Design Bending Moment

The design bending moment under factored load shall be taken as the maximum bending moment in the length of the member. It shall be determined either,

- a) directly from the second-order analysis; or
- b) approximately, if the member is divided into a sufficient number of elements, as the greatest of the element end bending moments, or;

- c) by amplifying the calculated design bending moment, taken as the maximum bending moment along the length of a member as obtained by superposition of the simple beam bending moments determined by the analysis.

For a member with zero axial force or a member subject to axial tension, the factored design bending moment shall be calculated as the moment obtained from second-order analysis without any amplification.

For a member with a design axial compressive force as determined from the analysis, the factored design bending moment shall be calculated as follows:

$$M = \delta_b M_m$$

where

δ_b = moment amplification factor for a braced member determined in accordance with **16**.

B-3 FRAME INSTABILITY ANALYSIS

B-3.1 Analysis

Frame instability, as treated here, is related to the design of multi-storey rigid-jointed frames subject to side sway. The elastic critical load factor, λ_{cr} may be determined using the deflection method as given in **B-3.2** or any other recognized method. This is used to calculate the amplified sway moments for elastic designs and to check frame stability in plastic designs. The elastic critical load factor, λ_{cr} of a frame is the ratio by which each of the factored loads would have to be increased to cause elastic instability.

B-3.2 Deflection Method

An accurate method of analysis (ordinary linear elastic analysis) should be used to determine the horizontal deflections of the frame due to horizontal forces applied at each floor level, which is equal to the notional horizontal load in **11.3.6**. Allowance should be made for the degree of rigidity of the base as given in **B-3.2** in this deflection calculation.

The base stiffness should be determined by reference to **11.3.4**.

The elastic critical load factor, λ_{cr} is calculated as:

$$\lambda_{cr} = \frac{1}{200\phi_{s, \text{Max}}}$$

where

$\phi_{s, \text{Max}}$ = largest value of the sway index where, ϕ_s given by:

$$\phi_{si} = \frac{\delta_{ui} - \delta_{Li}}{h_i}$$

where

h_i = storey height;

δ_{ui} = horizontal deflection of the top of the storey due to the combined gravity and notional loads; and

δ_{Li} = horizontal deflection of the bottom of the storey due to gravity and notional load.

B-3.3 Partial Sway Bracing

In any storey the stiffening effect of infill wall panels may be allowed for by introducing a diagonal strut in that storey of area A , given by:

$$A = \frac{k_3 \sum K_c}{h(h/b)} \left[1 + (h/b)^2 \right]^{3/2}$$

where

h = storey height;

b = width of the braced bay;

$\sum K_c$ = sum of the stiffness I/L , of the columns in that storey;

$$k_3 = \frac{h^2 \sum S_p}{80E \sum K_c} \leq 2; \text{ and}$$

$\sum S_p$ = Sum of spring stiffness (horizontal force per unit horizontal deflection of all the panels in that storey determined from:

$$S_p = \frac{0.6h/b}{\left[1 + (h/b)^2 \right]^2} t_p E_p$$

where

t_p = thickness of the wall panel, and

E_p = modulus of elasticity of the panel material.

ANNEX C

[Clauses 12.2.2.2 (b) and 12.6.2]

DESIGN AGAINST FLOOR VIBRATION**C-1 GENERAL**

Floor with longer spans of lighter construction and less inherent damping are vulnerable to vibrations under normal human activity. Natural frequency of the floor system corresponding to the lowest mode of vibration, damping characteristics, are important characteristics in floor vibration. Open web steel joists (trusses) or steel beams on the concrete deck may experience walking vibration problem. Fatigue, overloading of floor systems and vibrations due to rhythmic activities such as aerobic or dance classes are not within the scope of this annex.

C-2 ANNOYANCE CRITERIA

In the frequency range of 2 to 8 Hz in which people are most sensitive to vibration, the threshold level corresponds approximately to 0.5 percent g , where g is the acceleration due to gravity. Continuous vibration is generally more annoying than decaying vibration due to damping. Floor systems with the natural frequency less than 8 Hz in the case of floors supporting rhythmic activity and 5 Hz in the case of floors supporting normal human activity should be avoided.

C-3 FLOOR FREQUENCY

The fundamental natural frequency can be estimated by assuming full composite action, even in non-composite construction. This frequency, f_1 for a simply supported one way system is given by:

$$f_1 = 156 \sqrt{EI_T / WL^4}$$

where

E = modulus of elasticity of steel, in MPa;

I_T = transformed moment of inertia of the one way system (in terms of equivalent steel) assuming the concrete flange of width equal to the spacing of the beam to be effective, in mm⁴;

L = span length, in mm; and

W = dead load of the one way joist, in N/mm.

If the one way joist system is supported by a flexible beam running perpendicular with the natural frequency f_2 , the floor frequency may be reduced to f_r , given by:

$$\frac{1}{f_r^2} = \frac{1}{f_1^2} + \frac{1}{f_2^2}$$

C-4 DAMPING

The percentage of critical damping may be assumed approximately as given below:

<i>Sl No. (1)</i>	<i>System (2)</i>	<i>Critical Damping Percent (3)</i>
i)	Fully composite construction	2
ii)	Bare steel beam and concrete deck	3 - 4
iii)	Floor with finishes, false ceiling, fire proofing, ducts, furniture	6
iv)	Partitions not located along a support or not spaced farther apart than 6 m and partitions oriented in orthogonal directions	Up to 12

C-5 ACCELERATION

The peak acceleration a_0 , from heel impact for floors of spans greater than 7m and natural frequency f_1 , less than 10 Hz may be calculated as:

$$a_0/g = 600 f_1 / W$$

where

W = total weight of floors plus contents over the span length and equivalent floor width (b), in N;

$b = 40t_s$ (20 t_s when overhang is only on one side of the beam);

t_s = equivalent thickness of the slab, averaging concrete in slab and ribs; and

g = acceleration due to gravity.

ANNEX D
(Clause 14.2.2)**DETERMINATION OF EFFECTIVE LENGTH OF COLUMNS****D-1 METHOD FOR DETERMINING EFFECTIVE LENGTH OF COLUMNS IN FRAMES**

In the absence of a more exact analysis, the effective length of columns in framed structures may be obtained by multiplying the actual length of the column between the centres of laterally supporting members (beams) given in Fig. 27 and Fig. 28 with the effective length factor K , calculated by using the equations given below, provided the connection between beam and column is rigid type:

a) *Non-sway frames (Braced frame)* [(see 11.1.2 (a))]

A frame is designated as non-sway frame if the relative displacement between the two adjacent floors is restrained by bracings or shear walls (see 11.1.2). The effective length factor, K , of column in non-sway frames is given by (see Fig. 27):

$$K = \frac{[1 + 0.145(\beta_1 + \beta_2) - 0.265\beta_1\beta_2]}{[2 - 0.364(\beta_1 + \beta_2) - 0.247\beta_1\beta_2]}$$

b) *Sway frames (Moment Resisting Frames)* [see 11.1.2 (b)]

The effective length factor K , of column in sway frames is given by (see Fig. 28):

$$K = \left[\frac{1 - 0.2(\beta_1 + \beta_2) - 0.12\beta_1\beta_2}{1 - 0.8(\beta_1 + \beta_2) + 0.6\beta_1\beta_2} \right]^{0.5}$$

where

$$\beta_1, \beta_2 \text{ are given, } \beta = \frac{\sum K}{\sum K_c + \sum K_b}$$

K_c, K_b = Effective flexural stiffness of the columns and beams meeting at the joint at the ends of the columns and rigidly connected at the joints, and these are calculated by:

$$K = C (I / L)$$

I = moment of inertia of the member about an axis perpendicular to the plan of the frame,

L = length of the member equal to centre to centre distance of the intersecting member, and

C = correction factor as shown in Table 35.

Table 35 Correction Factors for Effective Flexural Stiffness

(Clause D-1)

SI No.	Far End Condition	Correction Factor, C	
		Braced Frame	Unbraced Frame
(1)	(2)	(3)	(4)
i)	Pinned	$1.5(1 - \bar{n})$	$1.5(1 - \bar{n})$
ii)	Rigidly connected to column	$1.0(1 - \bar{n})$	$1.0(1 - 0.2 \bar{n})$
iii)	Fixed	$2.0(1 - 0.4 \bar{n})$	$0.67(1 - 0.4 \bar{n})$

NOTE – $\bar{n} = \frac{P}{P_e}$

where

P_e = elastic buckling load, and
 P = applied load.

D-2 METHOD FOR DETERMINING EFFECTIVE LENGTH FOR STEPPED COLUMNS (see 14.2.2)

D-2.1 Single Stepped Columns

Effective length in the plane of stepping (bending about axis z-z) for bottom and top parts for single stepped column shall be taken as given in Table 36.

NOTE – The provisions of **D-2.1** are applicable to intermediate columns as well with stepping on either side, provided appropriate values of l_1 and l_2 are taken.

FIG. 27 COLUMN EFFECTIVE LENGTH FACTOR - NON SWAY FRAME

FIG. 28 COLUMN EFFECTIVE LENGTH FACTOR - SWAY FRAME

Table 36 Effective Length of Singled Stepped Columns
(Clause D-2.1)

SI No.	Degree of End Restraint	Sketch	Effective Length Coefficients	Column Parameters for all Cases
(1)		(2)	(3)	(4)
i)	Effectively held in position and restrained against rotation at both ends		$K_1 = \sqrt{\frac{K_{12}^2 + K_{11}^2(\alpha - 1)}{\alpha}}$ $K_2 = \frac{K_1}{C_1} \leq 3$ <p>where K_{12} and K_{11} are to be taken as per Table 37</p>	$\alpha = \frac{P_1 + P_2}{P_2}$ $C_1 = \frac{L_2}{L_1} \sqrt{\frac{I_1}{I_2 \alpha}}$ $\frac{i_2}{i_1} = \frac{L_2}{L_1} \times \frac{L_1}{L_1}$
ii)	Effectively held in position at both ends and restrained against rotation at bottom end only		$K_1 = \sqrt{\frac{K_{12}^2 + K_{11}^2(\alpha - 1)}{\alpha}}$ $K_2 = \frac{K_1}{C_1} \leq 3$ <p>where K_{12} and K_{11} are to be taken as per Table 38</p>	$\alpha = \frac{P_1 + P_2}{P_2}$ $C_1 = \frac{L_2}{L_1} \sqrt{\frac{I_1}{I_2 \alpha}}$ $\frac{i_2}{i_1} = \frac{L_2}{L_1} \times \frac{L_1}{L_1}$
iii)	Effectively held in position and restrained against rotation at bottom end, and top end held against rotation but not held in position		$K_1 \text{ to be taken as per Table 39}$ $K_2 = \frac{K_1}{C_1} \leq 3$	Effective length of bottom part of column in plane of stepping = $K_1 L_1$
iv)	Effectively held in position and restrained against rotation at bottom end, and top end neither held against rotation nor held in position		$K_1 \text{ to be taken as per Table 40}$ $K_2 = \frac{K_1}{C_1} \leq 3$	Effective length of top part of column in plane of stepping = $K_2 L_2$

D-3 Effective Length for Double Stepped Columns

Effective lengths in the plane of steppings (bending about axis z-z) for bottom, middle and top parts for a double stepped column shall be taken as follows (see also Fig. 29):

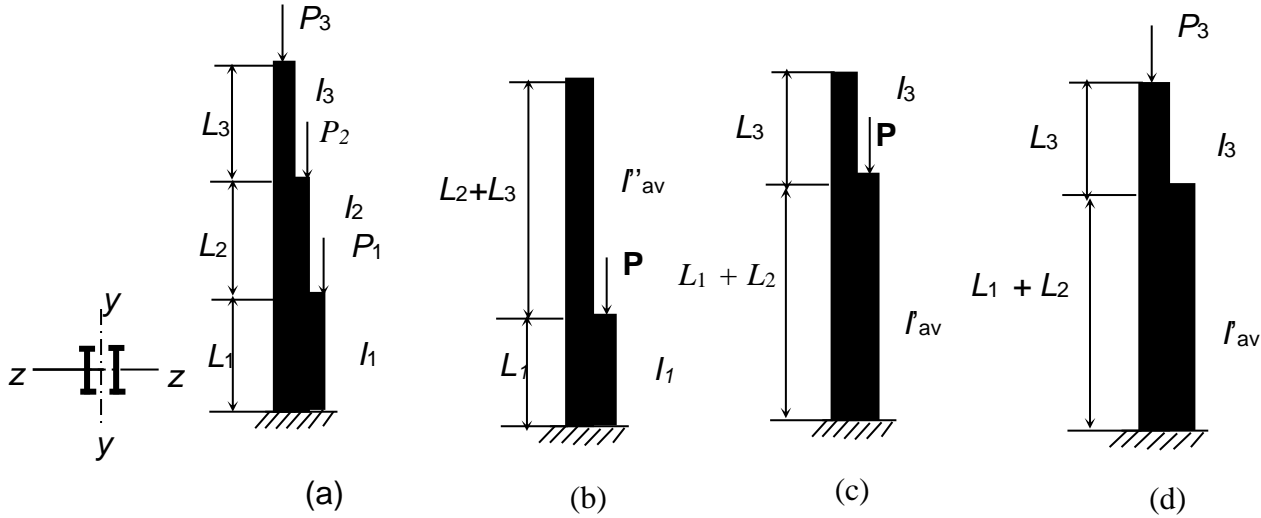

FIG. 29 EFFECTIVE LENGTH OF DOUBLE STEPPED COLUMNS

Coefficient K_1 for effective length of bottom part of double stepped column shall be taken from the formula:

$$K_1 = \sqrt{\frac{t_1 K_1^2 + (t_2 K_2^2 + K_3^2) \times (1 + n_2)^2 \times \frac{I_1}{I'_{av}}}{1 + t_1 + t_2}}$$

where

K_1 , K_2 , and K_3 are taken from Table 41.

$$t_1 = \frac{P_1}{P_3}, \quad t_2 = \frac{P_2}{P_3}, \quad n_2 = \frac{L_2}{L_1}$$

I'_{av} = average value of moment of inertia for the lower and middle parts

$$= \frac{I_1 L_1 + I_2 L_2}{L_1 + L_2}$$

I'_{av} = average value of moment of inertia for the middle and top parts

$$= \frac{I_2 L_2 + I_3 L_3}{L_2 + L_3}$$

Value of coefficient K_2 for middle part of column is given by formula:

$$K_2 = \frac{K_1}{C_2}, \text{ and}$$

Value of coefficient K_3 for the top part of the column is given by:

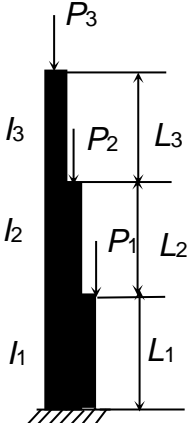

$$K_3 = \frac{K_1}{C_3} \leq 3$$

where

$$C_2 = \frac{L_2}{L_1} \sqrt{\frac{I_1(P_2 + P_3)}{I_2(P_1 + P_2 + P_3)}}, \quad C_3 = \frac{L_3}{L_1} \sqrt{\frac{I_1 P_3}{I_3(P_1 + P_2 + P_3)}}$$

NOTE – The provisions of **D-3.1** are applicable to intermediate columns as well with steppings on either side, provided appropriate values of I_1 , I_2 and I_3 are taken.

iv)	Effectively held in position and restrained against rotation at bottom end, and top end neither held against rotation nor against translation		$K_1 = 2$	$K_2 = 2$	$K_3 = K_1$ where K_1 is taken from Table 40 with $C_1 = \frac{L_3}{L_1 + L_2} \sqrt{\frac{I_{av}}{I_3}}$	

ANNEX E

(Clause 15.2.2.1)

ELASTIC LATERAL TORSIONAL BUCKLING**E-1 ELASTIC CRITICAL MOMENT****E-1.1 General**

The elastic critical moment is affected by the following:

- a) Moment gradient in the unsupported length,
- b) Boundary conditions at the lateral support points,
- c) Non-symmetric and non-prismatic nature of the member, and
- d) Location of transverse load with respect to shear centre.

The boundary conditions at the lateral supports have two components:

- 1) *Torsional restraint* – where the cross section is prevented from rotation about the shear centre, and
- 2) *Warping restraint* – where the flanges are prevented from rotating in their own plane about an axis perpendicular to the flange.

The elastic critical moment corresponding to lateral torsional buckling of a doubly symmetric prismatic beam subjected to uniform moment in the unsupported length and torsionally restraining lateral supports is given by:

$$M_{cr} = \frac{\pi^2 E I_y}{(L_{LT})^2} \left[\frac{I_w}{I_y} + \frac{G I_t (L_{LT})^2}{\pi^2 E I_y} \right]^{0.5}$$

where

I_y , I_w , I_t = moment of inertia about the minor axis, warping constant and St.Venant's torsion constant of the cross section, respectively (see IS 808 for properties of sections);

G = modulus of rigidity; and

L_{LT} = effective length against lateral torsional buckling (see **15.3**).

This equation in simplified form for I-section has been presented in **15.2.2.1**.

While the simplified equation is generally on the safe side, there are many situations where this may be very conservative. More accurate calculation of the elastic critical moment for general case of unsymmetrical sections, tapered members, loading away from shear centre and beams with moment gradient can be obtained from specialist literature, by using an appropriate computer program or equations given below.

E-1.2 Elastic Critical Moment of a Section Symmetrical About Minor Axis

In case of a beam which is symmetrical only about the minor axis, and bending about major axis, the elastic critical moment for lateral torsional buckling is given by the general equation below,

$$M_{cr} = c_1 \frac{\pi^2 E I_y}{(L_{LT})^2} \left\{ \left[\left(\frac{K}{K_w} \right)^2 \frac{I_w}{I_y} + \frac{G I_t (L_{LT})^2}{\pi^2 E I_y} + (c_2 y_g - c_3 y_j)^2 \right]^{0.5} - (c_2 y_g - c_3 y_j) \right\}$$

where

c_1, c_2, c_3 = factors depending upon the loading and end restraint conditions (see Table 42);

K = effective length factors of the unsupported length accounting for boundary conditions at the end lateral supports. The effective length factor K varies from 0.5 for complete restraint against rotation about weak axis to 1.0 for free rotate about weak axis, with 0.7 for the case of one end fixed and other end free. It is analogous to the effective length factors for compression members with end rotational restraint;

K_w = warping restraint factor. Unless special provisions to restrain warping of the section at the end lateral supports are made, K_w should be taken as 1.0;

y_g = y distance between the point of application of the load and the shear centre of the cross section and is positive when the load is acting towards the shear centre from the point of application;

$$y_j = y_s - 0.5 \int_A (z^2 + y^2)^2 y dA / I_z ;$$

y_s = coordinate of the shear centre with respect to centroid, positive when the shear centre is on the compression side of the centroid; and

y, z = coordinates of the elemental area with respect to centroid of the section.

y_j can be calculated by using the following approximation:

a) *Plain flanges:*

$$y_j = 0.8 (2\beta_f - 1) h_y / 2.0 \quad (\text{when } \beta_f > 0.5)$$

$$y_j = 1.0 (2\beta_f - 1) h_y / 2.0 \quad (\text{when } \beta_f \leq 0.5)$$

b) *Lipped flanges:*

$$y_j = 0.8 (2\beta_f - 1) (1 + h_L/h) h_y / 2 \quad (\text{when } \beta_f > 0.5)$$

$$y_j = (2\beta_f - 1) (1 + h_L/h) h_y / 2 \quad (\text{when } \beta_f \leq 0.5)$$

where

h_L = height of the lip,
 h = overall height of the section,
 h_y = distance between shear centre of the two flanges of the cross section, and
 $\beta_t = I_{fc} / (I_{fc} + I_{ft})$ where I_{fc} , I_{ft} are the moment of inertia of the compression and tension flanges, respectively, about the minor axis of the entire section.

I_t = St. Venant's Torsion constant, given by:

$$I_t = \sum b_i t_i^3 / 3 \quad (\text{for open section})$$

$$= 4A_e^2 / \sum (b/t) \quad (\text{for hollow section})$$

where

A_e = area enclosed by the section, and

b , t = breadth and thickness of the elements of the section, respectively.

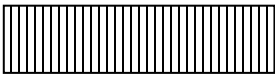

I_w = The warping constant, given by:

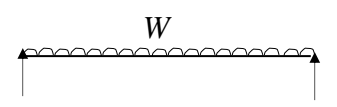

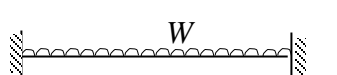

$$(1 - \beta_t) \beta_t I_y h_y^2 \quad (\text{for I-sections mono-symmetric about weak axis})$$

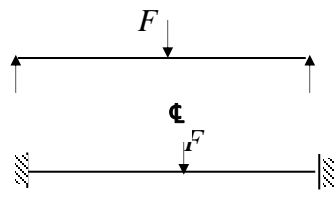

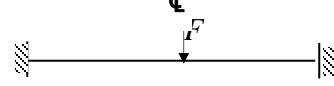

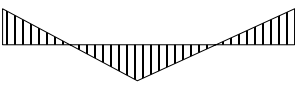

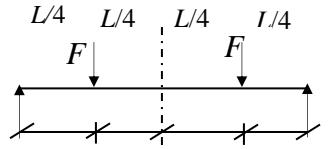

$$= 0 \quad (\text{for angle, Tee, narrow rectangle section and approximately for hollow sections})$$

ANNEX F (Clause 17.6.1)

CONNECTIONS

F-1 GENERAL

The requirement for the design of splice and beam to column connection as well as recommendation for their design shall be as given below.

F-2 BEAM SPLICES

F-2.1 For rolled section beam splices located away from the point of maximum moment, it may be assumed that the flange splice carries all the moment and the web splice carries the shear (see Fig. 30). However, in the case of a deep girder, the total moment may be divided between the flange and the web in accordance with the stress distribution. The web connection should then be designed to resist its share of moment and shear. Even web splice is designed to carry only shear force, the moment about the centroid of the bolt group on either side of the splice should be designed for moment due to eccentricity.

F-2.2 Flange joints should preferably not be located at points of maximum stress. Where splice plates are used, their area shall not be less than 5 percent in excess of the area of the flange element spliced; and their centre of gravity shall coincide, as nearly as possible with that of the element spliced. There shall be enough fasteners on each side of the splice to develop the load in the element spliced plus 5 percent but in no case should the strength developed be less than 50 percent of the effective strength of the material spliced. Wherever possible in welded construction, flange plates shall be joined by complete penetration butt welds. These butt welds shall develop the full strength of the plates. Whenever the flange width or thickness changes at the splice location, gradual transition shall be made in the width/thickness of the larger flange.

F-2.3 When beam splice is located at the point of inflection of a continuous beam, the flange splicing requirement given above may be relaxed appropriately.

FIG. 30 BEAM SPLICES

F-3 COLUMN SPLICE

F-3.1 Where the ends of compression members are faced for bearing over the whole area, they shall be spliced to hold the connected parts aligned. The ends of compression members faced for bearing shall invariably be machined to ensure perfect contact of surfaces in bearing (see Fig. 31).

F-3.2 Where such members are not faced for complete bearing the splices shall be designed to transmit all the forces to which the members is subjected at the splice location.

F-3.3 Wherever possible, splices shall be proportioned and arranged so that centroidal axis of the splice coincides as nearly as possible with the centroidal axes of the members joined, in order to avoid eccentricity; but where eccentricity is present in the joint, the resulting stress considering eccentricity shall be provided for.

F-3.4 If a column flange is subjected to significant tension or if the faces are not prepared for bearing, or if full continuity is required without slip, only HSFG bolts shall be used.

FIG. 31 COLUMN SPLICE (Typical)

F-4 BEAM-TO-COLUMN CONNECTIONS

F-4.1 Simple Connections

Simple connections are assumed to transfer only shear at some nominal eccentricity and typically used in frames up to about five stories in height, where strength rather than stiffness govern the design. In such frames separate lateral load resisting system is to be provided in the form of bracings or shear walls. The connections shown in Fig. 32

(a), (b), (c) and (d) can be assumed as simple connections in framed analysis and need to be checked only for the transfer of shear from beam to column.

F-4.2 Rigid Connections

In high-rise and slender structures, stiffness requirements may warrant the use of rigid connections. Rigid connections transfer significant moments to the columns and are assumed to undergo negligible deformations at the joint. These are necessary in sway frames for stability and also contribute in resisting lateral loads. The connections shown in Fig. 32 (e), (f), (g) can be assumed as rigid connection in frame analysis and need to be checked for both shear and moment transfer from beam to the column. Fully welded connections can also be considered as rigid beam to column connections.

F-4.3 Semi-rigid Connections

Semi-rigid connections fall between the two types mentioned above. The fact is that simple connections do have some degree of rotational rigidity as in the semi-rigid connections. Similarly rigid connections do experience some degree of joint deformation and this can be utilized to reduce the joint design moments.

The moment-rotation relationship of the connections have to be determined based on experiments conducted for the specific design or based on the relationship derived from tests, presented in specialist literature. The simplest method of analysis will be to idealize the connection as an equivalent rotational spring with either a bilinear or non-linear moment-rotation characteristics. The classification proposed by Bjorhovde combined with the Frye-Morris model can be used with convenience to model semi-rigid connections, as given in the next section.

F-4.3.1 Connection Classification

Connections are classified according to their ultimate strength or in terms of their initial elastic stiffness and Bjorhovde's classification. It is based on the non-dimensional moment parameter ($m^1 = M_u / M_{pb}$) and the non-dimensional rotation parameter ($\theta^1 = \theta_r / \theta_p$), where θ_p is the plastic rotation. The Bjorhovde's classification is based on a reference length of the beam equal to 5 times the depth of the beam. The limits used for connection classification are shown in Table 43 and are graphically represented in Fig. 33.

F-4.3.2 Connection Models

Frye-Morris has derived the following polynomial model for the moment curvature relationship of semi-rigid connections:

$$\theta = C_1(KM)^1 + C_2 (KM)^3 + C_3 (KM)^5$$

where

M = moment at the joint, in kN.m;

K = standardization parameter which depend on the connection type and geometry; and

C_1, C_2, C_3 = curve fitting constants

Table 44 shows the curve fitting constants and standardization constants for Frye-Morris Model [All size parameters in the table are in mm, (see Fig. 32)].

where

d = depth of beam, in mm.

d_a = depth of the angle, in mm.

d_b = diameter of the bolt, in mm.

d_g = center to center of the outermost bolt of the end plate connection, in mm.

g = gauge distance of bolt line, in mm.

t_a = thickness of the top angle, in mm.

t_c = thickness of the web angle, in mm.

t_f = thickness of flange T-stub connector, in mm.

t_w = thickness of web of the beam in the connection, in mm.

t_p = thickness of end plate, header plate, in mm.

l_a = length of the angle, in mm.

l_t = length of the T-stub connector, in mm.

NOTE – For preliminary analysis using a bilinear moment curvature relationship, the stiffness given in Table 45 may be assumed depending on the type of connection. The values are based on the secant stiffness at a rotation of 0.01 radian and typical dimension of connecting angle and other components as given in the table.

Table 45 Secant Stiffness
(Table 42)

SI No.	Type of Connection	Dimension mm	Secant Stiffness kNm/radian
(1)	(2)	(3)	(4)
i)	Single web connection angle	$d_a = 250$, $t_a = 10$, $g = 35$	1 150
ii)	Double web-angle connection	$d_a = 250$, $t_a = 10$, $g = 77.5$	4 450
iii)	Top and seat angle connection without double web angle connection	$d_a = 300$, $t_a = 10$, $l_a = 140$, $d_b = 20$	2 730
iv)	Header plate	$d_p = 175$, $t_p = 10$, $g = 75$, $t_w = 7.5$	2 300

F-5 COLUMN BASES**F-5.1 Base Plates**

Columns shall be provided with base plates capable of distributing the compressive forces in the compressed parts of the column over a bearing area such that the bearing pressure on the foundation does not exceed the design strength of the point. The design strength of the joint between the base plate and the foundation shall be determined taking account of the material properties and dimensions of both the grout and the concrete foundation.

F-5.2 Holding Down Bolts (Anchor Bolts)

F-5.2.1 Holding down bolts shall be provided if necessary to resist the effects of the design loads. They shall be designed to resist tension due to uplift forces and tension due to bending moments as appropriate.

F-5.2.2 When calculating the tension forces due to bending moments, the lever arm shall not be taken as more than the distance between the centroid of the bearing area on the compression side and the centroid of the bolt group on the tension side, taking the tolerances on the positions of the holding down bolts into account.

F-5.2.3 Holding down bolts shall either be anchored into the foundation by a hook or by a washer plate or by some other appropriate load distributing member embedded in the concrete.

F-5.2.4 If no special elements for resisting the shear force are provided, such as block or bar shear connectors, it shall be demonstrated that sufficient resistance to transfer the shear force between the column and the foundation is provided by one of the following:

- a) Frictional resistance of the joint between the base plate and the foundation.
- b) Shear resistance of the holding down bolts.
- c) Shear resistance of the surrounding part of the foundation.
- d) Shear and bearing resistance of the shear key plates welded to the base plate and embedded in the pedestal/foundation.

F-5.2.6 The detailed design of metal anchors in concrete is given in Annex G.

ANNEX G

(Foreword and Clause F-5.2.6)

DESIGN OF METAL ANCHORS IN CONCRETE

G-1 GENERAL

G-1.1 The design methods apply to design metal anchorages, such as headed studs, bolts with and without washers and hooked bolts having demonstrated pull out strength without benefit of friction.

G-1.2 The design methods cover single anchors and group of anchors as in Fig. 34, situated away from the edges and near the edges. Anchor group effect shall be considered whenever two or more anchors have spacing less than the minimum spacing required for their individual action. In an anchor group only anchors of the same type, size and length shall be used.

G-1.3 The concrete member in which the anchors are embedded shall be normal weight concrete of at least M 20 concrete and at most M 50 concrete grades. The anchor may be located in uncracked or cracked zones of the concrete.

G-1.4 The design method applies to anchors subjected to tension, shear or combined tension and shear due to static or quasi static loadings and not subjected to impact loadings, high cycle fatigue loading or loaded in compression. The design is for loads under in service conditions, rather than short-term handling and construction conditions. In case of an anchor group the individual anchors are loaded through a rigid fixture.

Fig. 34 (a) Anchorages situated far from concrete edges

Fig. 34 (b) ANCHORAGES SITUATED NEAR TO

FIG. 34 POSITION OF ANCHORS

G-2 LIMIT STATES

G-2.1 The design resistance, R_d , is given by

$$R_d = \frac{R_u}{\gamma_M}$$

where

R_u = ultimate resistances as given below for different failure modes

γ_M = Partial safety factor for resistance, as given in table 46 for different failure modes

Table 46 Partial Safety Factors for Resistance

SI No.	Limit State	Symbol	Value
i)	Steel under tension	γ_{Mst}	$= \frac{1.2}{f_{yas}/f_{uas}} \geq 1.4$
ii)	Steel under shear	γ_{Msv}	$= \frac{1.0}{f_{yas}/f_{uas}} \geq 1.25$ for $f_{uas} \leq 800$ MPa and $f_{yas}/f_{uas} \leq 0.8$ $= 1.5$ for $f_{uas} > 800$ MPa or $f_{yas}/f_{uas} > 0.8$
iii)	Concrete pyramid failure under tension	γ_{Mct}	$= 2.15$
iv)	Concrete splitting failure under tension	γ_{Mspt}	$= 2.15$
v)	Concrete cone failure under tension	γ_{Mcv}	$= 1.8$

vi)	Concrete splitting failure under tension	γ_{Mspt}	= 1.8
-----	--	-----------------	-------

G-2.2 Resistance of Anchor Under Tension

The Ultimate Limit State of an anchor or group of anchors may be governed by

- a) Steel anchor failure in tension
- b) Steel anchor pullout failure
- c) Concrete cone failure
- d) Concrete splitting failure

The design resistance of the anchor under tension, T_{da} , is taken as the smallest of the above limit states resistance divided by appropriate partial safety factor. Anchor pull out, concrete cone and splitting modes of failure associated with concrete, are non-ductile. Hence, it is desirable to have the design resistance due to steel anchor failure to be greater than the design resistance as governed by concrete failure.

G-2.2.1 Steel Anchor Failure in Tension

The design resistance governed by steel anchor failure in tension, T_{dsa} , is given by

$$T_{dsa} = \frac{A_{sn} f_{usa}}{\gamma_{Mst}}$$

where

A_{sn} = Net cross-sectional area of the steel anchor under tension

f_{uas} = Ultimate tensile strength of the anchor steel material

G-2.2.2 Steel Anchor Pullout failure

The anchor pullout failure is due to bearing failure of bolt head on the concrete and the corresponding design resistance, T_{dp} , is given by

$$T_{dp} = 6.4 \psi_{uctr} A_{brg} f_{ck}$$

ψ_{uctr} = factor that accounts for cracking of concrete in the anchorage zone

= 1.0 if the anchor is in cracked concrete zone

= 1.4 if the anchor is in non-cracked concrete zone

A_{brg} = Bearing area of the anchor head, washers etc. against concrete

F_{ck} = characteristic cube strength of concrete

G-2.2.3 Concrete Pyramid Failure

Concrete pyramid failure is due tensile failure of concrete along an idealised inverted pyramid having base angle of 35 ° and with the vertex at the base of the anchor as shown in Fig. 35. AS examples for group of anchors close to the edge of concrete base, the base areas of the idealised pyramids are shown in Fig. 35b. The design tensile strength of anchor as governed by concrete pyramid failure, T_{dca} , is given by

$$T_{dca} = \frac{7.2\sqrt{f_{ck}} h_{ef}^{1.5}}{\gamma_{Mct}} \frac{A_{ct}}{A_{ct}^0} \psi_{st} \psi_{ret} \psi_{ect} \psi_{ucrt}$$

where

f_{ck} = characteristic cube strength of concrete in MPa

h_{ef} = Effective anchorage depth

A_{ct} = Pyramid base area for the arrangement of anchors (see fig. 35b)

A_{ct}^0 = base area of the idealised pyramid in an isolated anchor (see fig. 35a)

ψ_{st} = factor that accounts for disturbance in stress distribution in concrete due to anchors at the edges of the concrete member

$$\psi_{st} = 0.7 + 0.3 \frac{c}{0.5 S_{cr}}$$

where

c = the smallest edge distance of the anchor

ψ_{ret} = shell spalling factor

$$\psi_{ret} = 0.5 + \frac{h_{ef}}{200} \quad \text{where } h_{ef} \text{ is expressed in mm}$$

$\psi_{ret} = 1.0$ (if in the area of anchorage, steel bars of diameter > 10 mm is spaced at 150 mm or bars of diameter ≤ 10 mm are spaced at 100 mm)

ψ_{ect} = factor to account for effect of unequal tension in a bolt group due to eccentric tension

$$\psi_{ect} = \frac{1}{1 + 2e_g/S_{cr}}$$

where e_g = eccentricity of the resultant tension on the group of anchors with respect to centroid of the group, to be taken as the product of the two eccentricity factors in case the eccentricity is in two directions.

Value of ψ_{ect} may be assumed as 1.0, if the calculated force from analysis in the most stressed anchor is compared with the value corresponding to the total resistance of the group (T_{dca}) divided by the number of fasteners in the group.

ψ_{uctr} = factor that accounts for cracking of concrete in the anchorage zone
 = 1.0 if the anchor is in cracked concrete zone
 = 1.4 if the anchor is in non-cracked concrete zone

Fig 35 (a) CONCRETE PYRAMID FAILURE OF AN ISOLATED ANCHOR

Fig 35 (b) EXAMPLES OF IDEALISED PYRAMID BASE FOR DIFFERENT GROUP ANCHOR ARRANGEMENT AT EDGE OF CONCRETE FOR TENSION LOADING

FIG. 35 CONCRETE PYRAMID FAILURE IS DUE TENSILE FAILURE OF CONCRETE

G-2.2.4 Concrete Splitting Failure

Splitting failure may be assumed as not to occur if all the edge distances $c \geq 2.25 h_{ef}$ and total concrete member depth at the anchor zone, $h \geq 2 h_{ef}$. Further, check for splitting resistance may be omitted if the following two conditions are met.

- Reinforcements are provided in the anchorage zone to limit the crack width to 0.3 mm
- Concrete pyramid failure and pull out failure resistances are calculated for cracked concrete

Otherwise, the design resistance to concrete splitting failure, T_{dcsp} , is evaluated as

$$T_{dcsp} = \frac{7.2 \sqrt{f_{ck}} h_{ef}^{1.5}}{\gamma_{Mct}} \frac{A_{ct}}{A_{ct}^0} \psi_{st} \psi_{ret} \psi_{ect} \psi_{ucrt} \psi_{hsp}$$

Where A_{ct} , A_{ct}^0 , ψ_{st} , ψ_{ret} , ψ_{ect} , ψ_{ucrt} are evaluated as in the concrete pyramid failure using S_{crsp} instead of S_{cr} .

ψ_{hsp} = factor to account for the influence of the actual depth of the member, h , on splitting resistance of anchors and is given by

$$\psi_{hsp} = \left(\frac{h}{2h_{ef}} \right)^{2/3} \leq 1.5$$

If the edge distance of an anchor is smaller than $0.5 S_{crsp}$, then longitudinal reinforcement along the edge of the member should be provided at the anchor location

G-2.3 Resistance of Anchor Under Shear

The ultimate resistance to anchor shear may be governed by

- Steel failure due to shear load without bending in anchor
- Steel failure with shear and bending in anchor
- Concrete pry-out failure
- Concrete edge failure

The design resistance of the anchor under shear, V_{da} , is taken as the smallest of the above limit states resistance divided by appropriate partial safety factor. Concrete pry-out and concrete edge failure associated with concrete, are non-ductile. Hence, it is desirable to have the design resistance due to steel anchor failure to be greater than design resistance as governed by concrete failure.

G-2.3.1 Steel Failure Due to Shear Load Without Bending In Anchor

The design shear resistance of the anchor as governed by steel failure, V_{das} , is given by

$$V_{das} = \frac{0.5 A_{sn} f_{usa}}{\gamma_{Msv}}$$

In case of anchor group made of steel with lower ductility ($\varepsilon_u < 8$ percent) the design shear resistance of the group shall be obtained by multiplying the above value by a factor of 0.8

G-2.3.2 Steel Failure with Shear and Bending in Anchor

Anchor bolts may be subjected to bending along with shear as shown in Fig. 36. The Moment, M_u , may be calculate as

$$M_u = V_u \frac{l}{\alpha_M}$$

where

l = lever arm as shown in Fig. 36, where a_3 = 0.5 times nominal diameter of the bolt

α_M = fixture rotational restrain factor

= 2.0 if fully restrained

= 1.0 if not restrained

The shear resistance with bending in anchor as governed by steel failure, V_{das} , is given by

The design shear resistance of the anchor as governed by steel failure, V_{das} , is given by smaller of the value as calculated above (governed by shear resistance of anchor) and the value given below (shear resistance as governed by flexure of anchor)

$$V_{das} = \frac{\alpha_M M_{dt}}{l \gamma_{Msv}}$$

where

$$M_{dt} = M_d^0 (1 - T_u / T_{dsa})$$

$$M_d^0 = 1.2 Z_{ea} f_{usa}$$

Z_{ea} elastic section modulus of the anchor

FIG. 36 LEVER ARM, l , OF ANCHOR**G-2.3.3 Concrete Pry-out Failure**

Anchorage with stiff anchors may fail by concrete behind the anchor bolt (at the side opposite to shear load). The design shear resistance as governed by concrete pry-out failure, V_{dcp} , is given by

$$V_{dcp} = k T_{dca}$$

where

$$k = 1 \quad \text{if } h_{ef} < 60 \text{ mm}$$

$$k = 2 \quad \text{if } h_{ef} \geq 60 \text{ mm}$$

T_{dca} = Design tension resistance of the anchor as governed by concrete pyramid failure (**G-2.2.3**)

G-2.3.4 Concrete Edge Failure

Anchorage failure due to concrete edge failure under shear may be disregarded if the edge distance from the anchor in the direction of shear is greater than $10h_{ef}$.

The design shear resistance of the anchor due to concrete edge shear, V_{dac} , maybe evaluated from,

$$V_{dac} = \frac{0.45 \sqrt{d_a} (h_{ef}/d_a)^{0.2} \sqrt{f_{ck}} c_1^{1.5}}{\gamma_{McV}} \frac{A_{cv}}{A_{cv}^0} \psi_{sv} \psi_{av} \psi_{ecv} \psi_{ucrv} \psi_{hv}$$

where

A_{cv}^0 = Area of concrete cone of an individual anchor (Fig. 37a)

A_{cv} = Actual area of a concrete cone considering group and edge effects (Fig. 37b)

D_a = Nominal diameter of an anchor

FIG. 37(A) IDEALISED CONCRETE CONE FOR EDGE

FIG. 37(B) EXAMPLES OF ACTUAL AREAS IDEALISED CONCRETE CONE FOR EDGE SHEAR

FIG. 37 AREA OF CONCRETE CONE

ψ_{sv} = factor that accounts for disturbance of distribution of concrete stresses at a corner (Fig. 4b) and is given by

$$\psi_{sv} = 0.7 + 0.3 \frac{c_2}{0.5c_1} \leq 1.0$$

ψ_{av} = factor that accounts for the angle α_v of the applied load and the direction perpendicular to the free edge of the concrete member (Fig)

$$\psi_{av} = 1.0 \quad \text{for } 0^\circ \leq \alpha_v \leq 55^\circ \quad (\text{area 1})$$

$$\psi_{av} = \frac{1.0}{(\cos \alpha_v + 0.5 \sin \alpha_v)} \quad \text{for } 55^\circ \leq \alpha_v \leq 90^\circ \quad (\text{area 2})$$

$$\psi_{av} = 2.0 \quad \text{for } 90^\circ \leq \alpha_v \leq 180^\circ \quad (\text{area 3})$$

ψ_{ecv} = factor that accounts for variation of shear force in different anchors of a group due to eccentricity, e_v , of resultant shear with respect to centroid of the group and is given by

$$\psi_{ecv} = \frac{1.0}{[1 + 2 e_v / (3c_1)]} \leq 1.0$$

Factor ψ_{ecv} assumed to be equal to 1.0 as a simplification if the most stressed anchor is checked against the average resistance of anchor shear resistance of the group.

The factor ψ_{ecv} accounts for cracking of concrete and reinforcement in the anchorage zone, as given below:

$\psi_{ecv} = 1.0$, anchorage in cracked concrete without edge reinforcement or stirrups

$\psi_{ecv} = 1.2$, anchorage in cracked concrete with straight edge reinforcement, diameter ≥ 12 mm

$\psi_{ecv} = 1.4$, anchorage in cracked concrete with edge reinforcement and closely spaced stirrups, at less than 100 mm spacing or anchorage in non-cracked concrete.

G-2.4 Resistance of Anchor under Combined Tension and Shear

The following interaction equation should be satisfied any anchor or anchor group under combined tension and shear

$$\left(\frac{T_{ua}}{T_{da}}\right)^{\alpha} + \left(\frac{V_{ua}}{V_{da}}\right)^{\alpha} \leq 1.0$$

where

$\alpha = 2.0$ when resistance is governed by steel failure

$\alpha = 1.5$ for all other failure modes

G-3 DESIGN OF ANCHORS SUBJECTED TO FORCES DUE TO EARTHQUAKE

If the tensile component of the limit states of strength level earthquake force experienced by a single anchor or group of anchors is less than or equal to 20 percent of the total factored anchor tensile force associated with the same tensile load combination, it is permitted to design the single anchor or group of anchors as required in **G-2**. Otherwise, the following requirements have to be satisfied.

G-3.1 Anchors and their attachment shall satisfy one of the following conditions (a) through (d):

- a) In single anchors, the concrete governed design resistance shall be greater than the expected steel governed strength, which shall be taken as 1.2 times the nominal strength, evaluated without considering the partial safety factor.

In case anchor group, the ratio of tensile load (action) on the most stressed anchor in the group to the steel design resistance of that anchor shall be greater than or equal to the ratio of the tensile load (action) on the anchors to the concrete-governed strength of anchors.

In addition, the following shall be satisfied:

- 1) Where anchors are subjected to load reversal (compression) the anchors shall be protected against buckling
 - 2) When connections are threaded and the ductile steel elements are not threaded over their entire length, the ratio of f_{uta}/f_{yta} shall not be less than 1.3, unless the threaded portions are upset.
 - 3) Anchors shall transmit tensile loads via a ductile steel element with a stretch length of at least eight times the anchor diameter. The upset portion shall not be included in the stretch length.
 - 4) Deformed reinforcing bars used as the ductile steel element shall be limited to 550MPa tensile strength.
- b) The anchor or group of anchors shall be designed for the maximum tension that can be transmitted based on the development of ductile yield mechanism in the attachment in tension, flexure, shear, bearing or a combination of these, considering the material over strength and and strain hardening effects for the attachment.
- c) The anchor or group of anchors shall be designed for the maximum force that can be transmitted to them by a non-yielding attachment.
- d) The anchor or group of anchors shall be designed for the maximum of force obtained by design load combinations that include increases the earthquake load by the prescribed over load factor, Ω_0 .

G-3.2 In evaluated the design resistance as governed by concrete, it shall be assumed that concrete is cracked, unless it is demonstrated otherwise.

ANNEX H

PLATE GIRDERS WITH CORRUGATED WEB

(Foreword)

H-1 FLEXURAL RESISTANCE

The overhang of the flange beyond the farthest face of the web at any section may be limited to that required by class 1, 2 and 3 sections, as given in table 2. Contribution of web in flexural resistance is disregarded as given below.

The flexural design resistance is given by

$$M_d = \text{Min} \left\{ \frac{b_c t_c f_{fc}}{\gamma_{m0}} \left(h_w + \frac{t_t + t_c}{2} \right); \frac{b_t t_t f_{ft}}{\gamma_{m0}} \left(h_w + \frac{t_t + t_c}{2} \right) \right\}$$

where

the dimensional symbols are shown in Fig. 38.

FIG. 38 ELEMENT DIMENSIONS OF PLATE GIRDER WITH CORRUGATED WEB

The design compressive stress, f_{fc} , is the minimum of yielding compressive stress after accounting for transverse (in-plane) bending of compression flange due to eccentric shear flow in the flange due to corrugated web as given below, or by lateral buckling of compression flange as given in **15.2.2**.

The yield strength after accounting for eccentric shear flow in the flanges is given by

$$f_{fc} = f_{yc} \sqrt{1 - \frac{4 M_{vc} \gamma_{m0}}{b_c^2 t_c f_{yc}}};$$

$$f_{ft} = f_{yt} \sqrt{1 - \frac{M_{vt} \gamma_{m0}}{M_{pf}}}$$

Where

f_{yc}, f_{yt} = Yield strength of the material in the tension and compression flanges respectively

M_{Pf} = Ultimate design resistance of the flange under in-plane bending

$$= t b^3 f_{yf} / 4 \text{ for plastic and compact flanges, } t b^3 f_{yf} / 6$$

M_{vc}, M_{vt} = in-plane transverse bending moment in the tension and compression flange, respectively due to eccentric shear force from the web as shown in Fig. 39, and is evaluated from

$$M_{vc} = \frac{V y_c b_c t_c l_1 l_3}{2 I_z},$$

$$M_{vt} = \frac{V y_t b_t t_t l_1 l_3}{2 I_z}$$

Where

V = Shear force at the section of the girder

I_z = Moment of inertia about the major axis of the section disregarding the corrugated web.

y_c, y_t = Distance of the centroid of the compression and tension flange, respectively, from the neutral axis of the girder

FIG. 39 IN-PLANE TRANSVERSE BENDING MOMENT IN FLANGES DUE ECCENTRIC SHEAR FLOW FROM THE WEB

H-2 SHEAR RESISTANCE

The design shear resistance of the web, V_d , is given by

$$V_d = V_n / \gamma_{m0}$$

where

$$V_n = h_w t_w \chi_v f_{yw} / \sqrt{3}$$

where

h_w, t_w, f_{yw} = depth, thickness and yield strength of the web

χ_v = Shear stress reduction factor to account for web buckling, and is the smallest of local buckling χ_{vl} , global buckling, χ_{vg} , or interaction buckling, χ_{vlg} , of the web under shear, evaluated as given below.

$$\chi_v = \min (\chi_{vl}, \chi_{vg}, \chi_{vlg})$$

The shear stress reduction factor for local buckling of the web is evaluated as,

$$\chi_{vl} = 1.0 \quad \text{when } \lambda_{wl} \leq 0.8,$$

$$\chi_{vl} = [1 - 0.8(\lambda_{wl} - 0.8)] \quad \text{when } 0.8 < \lambda_{wl} < 1.2,$$

$$\chi_{vl} = \frac{1}{\sqrt{3} \lambda_{wl}^2} \quad \text{when } \lambda_{wl} \geq 1.2,$$

where

$$\lambda_{wl} = \sqrt{f_{yw}/(\sqrt{3}\tau_{cr,l})}$$

$$\tau_{cr,l} = \frac{k_v \pi^2 E}{12(1-\mu^2)(h_w/t_w)^2}$$

$$k_v = 4.0 + 5.35 \left(\frac{c}{h_w}\right) \quad \text{when } (c/h_w) < 1.0$$

$$k_v = 5.35 + 4.0 \left(\frac{c}{h_w}\right) \quad \text{when } (c/h_w) \geq 1.0$$

where

c is larger of l_1 and l_2 of corrugated web (See fig. 39)

In case of sinusoidally corrugated webs $\tau_{cr,e}$ may be evaluated using

$$\tau_{cr,l} = \left(5.35 + \frac{l_3 s}{h_w t_w}\right) \frac{\pi^2 E}{12(1-\mu^2)(s/t_w)^2}$$

The shear stress reduction factor for global buckling of the web is evaluated as,

$$\chi_{vg} = \frac{1.5}{(0.5 + \lambda_{wg}^2)} \leq 1.0$$

$$\lambda_{wg} = \sqrt{f_{yw}/(\sqrt{3}\tau_{cr,g})}$$

$$\tau_{cr,g} = \frac{32.4}{t_w h_w^2} \sqrt[4]{D_x D_z^3}$$

$$D_x = \frac{E t_w^3}{12(1-\mu^2)} \frac{w}{s} \quad \text{for sinusoidal corrugation}$$

$$D_x = \frac{E t_w^3}{12(1-\mu^2)} \frac{w}{(l_1 + l_2)} \quad \text{for profiled corrugation}$$

$$D_z = \frac{E I_z}{w}$$

I_z = second moment of area of one corrugation of length w

The shear stress reduction factor for global buckling of the web is evaluated as,

$$\chi_{vlg} = \frac{\chi_{vl} \times \chi_{vg}}{\sqrt{\chi_{vl}^2 + \chi_{vg}^2}} \leq 1.0$$

The reduction in shear resistance of the web due to the moment at the section need not be considered, since its contribution to flexure is not considered.

H-3 RESISTANCE TO CONCENTRATED LOAD

The design for bearing resistance under concentrated load and reactions may be carried out as required in **15.7**

ANNEX J
(Clause 24.16)

**GENERAL RECOMMENDATIONS FOR STEELWORK TENDERS AND
CONTRACTS**

J-1 GENERAL

J-1.1 The recommendations given in this annex are in line with those generally adopted for steelwork construction and are meant for general information.

J-1.2 These recommendations do not form part of the requirements of the Section and compliance with these is not necessary for the purpose of complying with this Section.

J-1.3 The recommendations are unsuitable for inclusion as a block requirement in a contract, but in drawing up a contract the points mentioned should be given consideration.

J-2 EXCHANGE OF INFORMATION

Before the steelwork design is commenced, the building designer should be satisfied that the planning of the building, its dimensions and other principal factors meet the requirements of the building owner and comply with regulations of all authorities concerned. Collaboration of building designer and steelwork designer should begin at the outset of the project by joint consideration of the planning and of such questions as the stanchion spacing, materials to be used for the construction, and depth of basement.

J-3 INFORMATION REQUIRED BY THE STEELWORK DESIGNER

J-3.1 General

- a) Site plans showing in plan and elevation of the proposed location and main dimensions of the building or structure;
- b) Ground levels, existing and proposed;
- c) Particulars of buildings or other constructions which may have to remain on the actual site of the new building or structure during the erection of the steelwork;
- d) Particulars of adjacent buildings affecting, or affected by, the new work;
- e) Stipulation regarding the erection sequence or time schedule;
- f) Conditions affecting the position or continuity of members;
- g) Limits of length and weight of steel members in transit and erection;
- h) Drawings of the substructure, proposed or existing, showing:
 - 1) levels of stanchion foundations, if already determined;
 - 2) any details affecting the stanchion bases or anchor bolts;
 - 3) permissible bearing pressure on the foundation; and
 - 4) provisions for grouting.

NOTE— In the case of new work, the substructure should be designed in accordance with the relevant standards dealing with foundations and substructure.

- j) The maximum wind velocity appropriate to the site (see Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code); and
- k) Environmental factors, such as proximity to sea coast, and corrosive atmosphere. Reference to bye-laws and regulations affecting the steelwork design and construction.

J-3.2 Further Information Relating to Buildings

- a) Plans of the floors and roof with principal dimensions, elevations and cross sections showing heights between floor levels.
- b) The occupancy of the floors and the positions of any special loads should be given.
- c) The building drawings, which should be fully dimensioned, should preferably be to the scale of 1 to 100 and should show all stairs, fire escapes, lifts, etc, suspended ceilings, flues and ducts for heating and ventilating. Doors and windows should be shown, as the openings may be taken into account in the computations of dead load.
Requirements should be given in respect of any maximum depth of beams or minimum head room.
Large-scale details should be given of any special features affecting the steelwork.
- d) The inclusive weight per m² of walls, floors, roofs, suspended ceilings, stairs and partitions, or particulars of their construction and finish for the computation of dead load.
The plans should indicate the floors, which are to be designed to carry partitions. Where the layout of partitions is not known, or a given layout is liable to alteration, these facts should be specially noted so that allowance may be made for partitions in any position (see Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code).
- e) The superimposed loads on the floors appropriate to the occupancy, as given in Part 6 'Structural Design', Section 1 'Loads, Forces and Effects' of the Code or as otherwise required.
- f) Details of special loads from cranes, runways, tips, lifts, bunkers, tanks, plant and equipment.
- g) The grade of fire resistance appropriate to the occupancy as may be required.

J-4 INFORMATION REQUIRED BY TENDERER (IF NOT ALSO DESIGNER)

J-4.1 General

- a) All information listed under **J-3.1**;
- b) Climatic conditions at site-seasonal variations of temperature, humidity, wind velocity and direction;
- c) Nature of soil. Results of the investigation of sub-soil at site of building or structure;

- d) Accessibility of site and details of power supply;
- e) Whether the steelwork contractor will be required to survey the site and set out or check the building or structure lines, foundations and levels;
- f) Setting-out plan of foundations, stanchions and levels of bases;
- g) Cross sections and elevations of the steel structure, as necessary, with large-scale details of special features;
- h) Whether the connections are to be bolted, riveted or welded. Particular attention should be drawn to connections of a special nature, such as turned bolts, high strength friction grip bolts, long rivets and overhead welds;
- j) Quality of steel, and provisions for identification;
- k) Requirements in respect of protective paintings at works and on site, galvanizing or cement wash;
- m) Approximate dates for commencement and completion of erection;
- n) Details of any tests which have to be made during the course of erection or upon completion; and
- p) Schedule of quantities. Where the tenderer is required to take off quantities, a list should be given of the principal items to be included in the schedule.

J-4.2 Additional Information Relating to Buildings

- a) Schedule of stanchions giving sizes, lengths and typical details of brackets, joints, etc;
- b) Plan of grillages showing sizes, lengths and levels of grillage beams and particulars of any stiffeners required;
- c) Plans of floor beams showing sizes, lengths and levels eccentricities and end moments. The beam reactions and details of the type of connection required should be shown on the plans;
- d) Plan of roof steelwork. For a flat roof, the plan should give particulars similar to those of a floor plan. Where the roof is pitched, details should be given of trusses, portals, purlins, bracing, etc;
- e) The steelwork drawings should preferably be to a scale of 1 to 100 and should give identification marks against all members; and
- f) Particulars of holes required for services, pipes, machinery fixings, etc. Such holes should preferably be drilled at works.

J-4.3 Information Relating to Execution of Building Work

- a) Supply of materials;
- b) Weight of steelwork for payment;
- c) Wastage of steel;
- d) Insurance, freight and transport from shop to site;
- e) Site facilities for erection;
- f) Tools and plants;
- g) Mode and terms of payment;
- h) Schedules;

- j) *Force Majeure* (sections and provisions for liquidation and damages for delay in completion); and
- k) Escalation sections.

J-5 DETAILING

In addition to the number of copies of the approved drawings or details required under the contract, dimensioned shop drawings or details should be submitted in duplicate to the engineer who should retain one copy and return the other to the steel supplier or fabricators with his comments, if any.

J-6 TIME SCHEDULE

As the dates on which subsequent trades can commence, depend on the progress of erection of the steel framing, the time schedule for the latter should be carefully drawn up and agreed to by the parties concerned at a joint meeting.

J-7 PROCEDURE ON SITE

The steelwork contractor should be responsible for the positioning and levelling of all steelwork. Any checking or approval of the setting out by the general contractor or the engineer should not relieve the steelwork contractor of his responsibilities in this respect.

J-8 INSPECTION

References may be made to the good practice [6-6A(42)] for general guidance.

J-8.1 Access to Contractor's Works

The contractor should offer facilities for the inspection of the work at all stages.

J-8.2 Inspection of Fabrication

Unless otherwise, agreed, the inspection should be carried out at the place of fabrication. The contractor should be responsible for the accuracy of the work and for any error, which may be subsequently discovered.

J-8.3 Inspection on Site

To facilitate inspection, the contractor should during all working hours, have a foreman or properly accredited charge hand available on the site, together with a complete set of contract drawings and any further drawings and instructions which may have been issued from time to time.

J-9 MAINTENANCE

J-9.1 General

Where steelwork is to be encased in solid concrete, brickwork or masonry, the question of maintenance should not arise, but where steelwork is to be housed in hollow fire protection or is to be unprotected, particularly where the steelwork is exposed to a corroding agent, the question of painting or protective treatment of the steelwork should be given careful consideration at the construction stage, having regard to the special circumstances of the case.

J-9.2 Connections

Where connections are exposed to a corroding agent, they should be periodically inspected, and any corroded part should be thoroughly cleaned and painted.

J-9.2.1 Where bolted connections are not solidly encased and are subject to vibratory effects of machinery or plant, they should be periodically inspected and all bolts tightened.

LIST OF STANDARDS

The following list records those standards which are acceptable as 'good practice' and 'accepted standards' in the fulfillment of the requirements of the Code. The latest version of a standard shall be adopted at the time of enforcement of the Code. The standards listed may be used by the Authority as a guide in conformance with the requirements of the referred clauses in the Code.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Part/Section.

(1)	786:1967	Conversion factors and conversion tables (<i>first revision</i>)
(2)	808 : 2021	Dimensions for hot-rolled steel beam, column, channel and angle sections (<i>fourth revision</i>)
	1852 : 1985	Rolling and cutting tolerance for hot rolled steel products (<i>fourth revision</i>)
	12779 : 2004	Rolling and cutting tolerance for parallel flange hot rolled steel products (<i>fourth revision</i>)
(3)	IS 8000	Geometrical tolerancing on technical drawings (<i>second revision</i>)
	(Part 1):1985	Tolerances of form, orientation, location and run-out, and appropriate geometrical definitions (<i>first revision</i>)
	(Part 2):1992	Maximum material principles (<i>first revision</i>)
	(Part 3):1992	Dimensioning and tolerancing of profiles (<i>second revision</i>)
	(Part 4):1976	Practical examples of indications on drawings
	IS 8976:1978	Guide for preparation and arrangement of sets of drawings and parts list
	962 : 1989	Code of practice for architectural and building drawings (<i>second revision</i>)
(4)	962 : 1989	Code of practice for architectural and building drawings (<i>second revision</i>)
